Recommendations for Preconception Care

MICHAEL C. LU, MD, MPH, University of California, Los Angeles, David Geffen School of Medicine and School of Public Health, Los Angeles, California

Every woman of reproductive age who is capable of becoming pregnant is a candidate for preconception care, regardless of whether she is planning to conceive. Preconception care is aimed at identifying and modifying biomedical, behavioral, and social risks through preventive and management interventions. Key components include risk assessment, health promotion, and medical and psychosocial interventions. Patients should formulate a reproductive life plan that outlines personal goals about becoming pregnant based on the patient’s values and resources. Preconception care can be provided in the primary care setting and through activities linked to schools, workplaces, and the community. (Am Fam Physician 2007;76:397-400. Copyright © 2007 American Academy of Family Physicians.)

For more than two decades, prenatal care has been a cornerstone for improving pregnancy outcomes in the United States. In recent years, however, limits to prenatal care and the importance of maternal health before pregnancy have been increasingly recognized.1 The Centers for Disease Control and Prevention (CDC) and the Agency for Toxic Substances and Disease Registry recently released recommendations to promote preconception care in the United States.2 The recommendations are summarized in Table 1; the full guideline is available at http://www.cdc.gov/mmwr/preview/mmwrhtml/rr5506a1.htm.

Components of Preconception Care

Every woman of reproductive age who is capable of becoming pregnant is a candidate for preconception care, even if she is not planning to conceive. Men should also receive preconception care, although the components are not as well defined in men as they are in women. The CDC defines preconception care as a set of interventions that aim to identify and modify biomedical, behavioral, and social risks to a woman’s health or pregnancy outcome through prevention and management.2 Several preconception care models have been developed.3,5 The American Academy of Pediatrics and the American College of Obstetricians and Gynecologists classify the main components of preconception care into four categories: physical assessment, risk screening, vaccinations, and counseling.6 Most components of preconception care (Table 2) can be addressed in the primary care setting. Checklists, references, continuing education resources, and patient information are available through a number of Web sites (e.g., http://www.marchofdimes.com/professionals/preconception.asp, http://www.cdc.gov/ncbddd/preconception/default.htm, http://www.aafp.org/afp/20020615/2507.html).

Interventions

Targeted interventions have been effective for patients who wish to conceive. Interventions include folic acid supplementation, testing for rubella seronegativity and vaccination if indicated, tight control of pregestational diabetes, careful management of hypothyroidism, and avoidance of teratogenic agents (e.g., isotretinoin [Accutane], warfarin [Coumadin], some antiseizure medications, alcohol, tobacco).10 By the time pregnant women have their first prenatal visit, it may be too late to prevent some placental development problems or birth defects. Organogenesis begins early in pregnancy; therefore, initiating folic acid supplementation after neural tube closure at six weeks (28 days after conception) has no demonstrated benefit for preventing a neural tube defect.13 Placental development begins even earlier, at implantation (seven days after conception). Poor placental development has been linked to preeclampsia and perterm birth14 and may play a role in fetal programming of chronic diseases later in life.15
During early prenatal care, it is often too late to restore allostasis\textsuperscript{16} (i.e., the body’s ability to maintain stability through change\textsuperscript{17}). Examples of allostasis include feedback inhibition in the hypothalamic-pituitary-adrenal (HPA) axis to regulate stress response\textsuperscript{17} and counterregulation of the immune system by the HPA axis to modulate inflammatory response.\textsuperscript{18} Chronic psychological or biologic stress can wear out these systems. Women who enter pregnancy with worn-out allostatic systems (e.g., dysregulated stress or inflammatory response) may be more susceptible to pregnancy complications, including preterm birth. Therefore, restoring allostasis is an important objective of preconception care.

<table>
<thead>
<tr>
<th>Risk assessment</th>
<th>Health promotion</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Reproductive life plan</strong>: Ask your patient if she plans to have children (or additional children if she is already a mother) and how long she plans to wait until she becomes pregnant; help her develop a plan, based on her values and resources, to achieve those goals</td>
<td><strong>Family planning</strong>: Promote family planning based on the patient’s reproductive life plan; for women who are not planning to become pregnant, promote effective contraceptue use and discuss emergency contraception</td>
</tr>
<tr>
<td><strong>Reproductive history</strong>: Review previous adverse pregnancy outcomes (e.g., infant death, fetal loss, birth defects, low birth weight, preterm birth) and assess ongoing biobehavioral risks that could lead to recurrence in a subsequent pregnancy</td>
<td><strong>Healthy weight and nutrition</strong>: Promote a healthy prepregnancy weight (ideal BMI is 19.8 to 26.0 kg per m²) through exercise and nutrition; discuss macro- and micronutrients, including getting “five-a-day” (i.e., two servings of fruit and three servings of vegetables) and taking a daily multivitamin that contains folic acid</td>
</tr>
<tr>
<td><strong>Medical history</strong>: Ask if the patient has a history of conditions that could affect future pregnancies (e.g., rheumatic heart disease, thromboembolism, autoimmune diseases); screen for ongoing chronic conditions such as hypertension and diabetes</td>
<td><strong>Healthy behaviors</strong>: Promote healthy behaviors such as nutrition, exercise, safe sex, effective contraceptive use, dental flossing, and use of preventive health services; discourage risky behaviors such as douching, not wearing a seatbelt, smoking (e.g., use the five A's [Ask, Advise, Assess, Assist, Arrange] for smoking cessation), and alcohol and substance abuse</td>
</tr>
<tr>
<td><strong>Medication use</strong>: Review the patient’s current medication use; avoid FDA pregnancy category X medications and most category D medications unless potential maternal benefits outweigh fetal risks; review the use of over-the-counter medications, herbs, and supplements</td>
<td><strong>Stress resilience</strong>: Promote nutrition, exercise, sufficient sleep, and relaxation techniques; address ongoing stresses (e.g., domestic violence); identify resources to help the patient develop problem-solving and conflict-resolution skills, positive mental health, and strong relationships</td>
</tr>
<tr>
<td><strong>Infections and immunizations</strong>: Screen for periodontal, urogenital, and sexually transmitted infections as indicated; update immunization with hepatitis B, rubella, varicella, Tdap, human papillomavirus, and influenza vaccines as needed; counsel the patient about preventing TORCH infections</td>
<td><strong>Healthy environments</strong>: Discuss household, neighborhood, and occupational exposures to heavy metals, organic solvents, pesticides, endocrine disruptors, and allergens; give practical tips such as how to avoid exposures</td>
</tr>
<tr>
<td><strong>Genetic screening and family history</strong>: Assess the patient’s risk of chromosomal or genetic disorders based on family history, ethnic background, and age; offer cystic fibrosis and other carrier screening as indicated; discuss management of known genetic disorders (e.g., phenylketonuria, thrombophilia) before and during pregnancy</td>
<td><strong>Interconception care</strong>: Promote breastfeeding, placing infants on their backs to sleep to reduce the risk of sudden infant death syndrome, positive parenting behaviors, and the reduction of ongoing biobehavioral risks</td>
</tr>
<tr>
<td><strong>Nutritional assessment</strong>: Assess the ABCDs of nutrition: anthropometric factors (e.g., BMI), biochemical factors (e.g., anemia), clinical factors, and dietary risks</td>
<td><strong>Medical and psychosocial interventions for identified risks</strong></td>
</tr>
<tr>
<td><strong>Substance abuse</strong>: Ask the patient about tobacco, alcohol, and drug use; use CAGE2 or T-ACE3 questionnaires to screen for alcohol and substance abuse</td>
<td>Interventions should address identified medical and psychosocial risks; examples include folic acid supplementation, testing for rubella seronegativity and vaccination if indicated, tight control of pregestational diabetes, careful management of hypothyroidism, and avoidance of teratogenic agents (e.g., isotretinoin [Accutane], warfarin [Coumadin], some antiseizure medications, alcohol, tobacco)¹⁰</td>
</tr>
<tr>
<td><strong>Toxins and teratogenic agents</strong>: Counsel the patient about possible toxins and exposure to teratogenic agents at home, in the neighborhood, and in the workplace (e.g., heavy metals, solvents, pesticides, endocrine disruptors, allergens); review Material Safety Data Sheets and consult a local teratology information specialist (<a href="http://otispregnancy.org/otis_find_a_tis.asp">http://otispregnancy.org/otis_find_a_tis.asp</a>) as needed</td>
<td><strong>Behavioral counseling</strong>: Educate the patient about behavioral changes that could improve health outcomes and reduce the risk of adverse events during pregnancy. This may include strategies for stress management, nutrition, exercise, and smoking cessation.</td>
</tr>
<tr>
<td><strong>Psychosocial concerns</strong>: Screen for depression, anxiety, domestic violence, and major psychosocial stressors</td>
<td><strong>Potential interventions</strong>: If behavioral counseling is not sufficient, consider the use of medication therapy, counseling, or other interventions to address identified psychosocial concerns.</td>
</tr>
<tr>
<td><strong>Physical examination</strong>: Focus on periodontal, thyroid, heart, breast, and pelvic examinations</td>
<td><strong>Stress resilience</strong>: Promote nutrition, exercise, sufficient sleep, and relaxation techniques; address ongoing stresses (e.g., domestic violence); identify resources to help the patient develop problem-solving and conflict-resolution skills, positive mental health, and strong relationships</td>
</tr>
<tr>
<td><strong>Laboratory testing</strong>: Testing should include a complete blood count; urinalysis; blood type and screen; and, when indicated, screening for rubella, syphilis, hepatitis B, human immunodeficiency virus, gonorrhea, chlamydia, and diabetes and cervical cytology; consider measuring thyroid-stimulating hormone levels</td>
<td><strong>Healthy environments</strong>: Discuss household, neighborhood, and occupational exposures to heavy metals, organic solvents, pesticides, endocrine disruptors, and allergens; give practical tips such as how to avoid exposures</td>
</tr>

</table>

FDA = U.S. Food and Drug Administration; Tdap = tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis; TORCH = Toxoplasmosis, Other viruses, Rubella, Cytomegaloviruses, Herpes (simplex) viruses; BMI = body mass index; CAGE = Cut down on drinking, Annoyance with criticisms about drinking, Guilt about drinking, and using alcohol as an Eye opener; T-ACE = Tolerance, Annoyance, Cut down, Eye-opener.

Information from references 1, and 3 through 12.

In addition to targeting optimal health outcomes for the baby, preconception care should promote the mother’s health, regardless of her plans for future pregnancies. Evidence suggests that pregnancy complications such as preeclampsia or preterm birth may increase the mother’s risk of chronic diseases later in life.¹⁹

**Implementation**

Preconception care includes more than a single pre pregancy office visit and less than all well-woman examinations²⁰; however, there is no consensus on this. For some physicians, preconception care is a single pre pregnancy checkup a few months before the patient attempts to conceive. A single visit, however,
may not be sufficient to address every preconception issue, and approximately one half of all pregnancies in the United States that are unintended at conception will be missed during the visit. For other physicians, preconception care includes all well-woman examinations and primary care visits from prepubescence to menopause. In practice, however, such frequent assessments may not be feasible or reimbursable, and some components (e.g., genetic and laboratory testing) may not be indicated or appropriate at every visit.

Physicians can start by asking female patients at every visit about their reproductive life plan (i.e., a plan, based on the patient’s values and resources, to achieve a set of personal goals about having children). The questions should include whether the patient intends to have a child (or additional children if she is already a mother) and her timeline for having children. If the patient plans to have a child within the next year or two, she and her partner should return for a full assessment.

Follow-up visits should be scheduled according to the patient’s individual risks. If the patient does not plan to become pregnant in the next one to two years or does not plan to have children, she should continue to receive well-woman examinations, which include routinely addressing her family planning needs and updating her reproductive life plan.

A survey of family physicians and obstetricians/gynecologists found that only one in six had provided preconception care to most women for whom they provided prenatal care. In addition to family physicians and obstetricians/gynecologists, other health care professionals (e.g., health educators, social workers) should be prepared to contribute to comprehensive preconception care. Preconception health can be promoted at workplaces, at schools, and in the community.

The author thanks Hani Atrash, MD, MPH; Brian Jack, MD; Kay Johnson, MPH; and Sam Posner, PhD, for their assistance in the preparation of this manuscript.

The Author

MICHAEL C. LU, MD, MPH, is an associate professor of obstetrics and gynecology at the David Geffen School of Medicine at the University of California, Los Angeles, (UCLA) and is an associate professor of community health sciences at the UCLA School of Public Health. He also is a member of the Centers for Disease Control and Prevention’s Panel on Preconception Care. Dr. Lu received his medical degree from the University of California, San Francisco, and completed an obstetrics and gynecology residency at the University of California, Irvine, Medical Center.
