Chronic Pelvic Pain in Women

DAVID D. ORTIZ, MD, CHRISTUS Santa Rosa Family Medicine Residency Program, San Antonio, Texas

The etiology of chronic pelvic pain in women is poorly understood. Although a specific diagnosis is not found in the majority of cases, some common diagnoses include endometriosis, adhesions, irritable bowel syndrome, and interstitial cystitis. The initial history and physical examination can narrow the diagnostic possibilities, guide any subsequent evaluation, and rule out malignancy or significant systemic disease. If the initial evaluation does not reveal a specific diagnosis, a limited laboratory and ultrasound evaluation can clarify the diagnosis, as well as rule out serious disease and reassure the patient. Few treatment modalities have demonstrated benefit for the symptoms of chronic pelvic pain. The evidence supports the use of oral medroxyprogesterone, goserelin, adhesiolysis for severe adhesions, and a multidisciplinary treatment approach for patients without a specific diagnosis. Less supporting evidence is available for oral analgesics, combined oral contraceptive pills, gonadotropin-releasing hormone agonists, intramuscular medroxyprogesterone, trigger point and botulinum A toxin injections, neuromodulative therapies, hormone agonists, intramuscular medroxyprogesterone, goserelin, adhesiolysis for severe adhesions, and a multidisciplinary treatment approach for patients without a specific diagnosis. Less supporting evidence is available for oral analgesics, combined oral contraceptive pills, gonadotropin-releasing hormone agonists, intramuscular medroxyprogesterone, trigger point and botulinum A toxin injections, neuromodulative therapies, and hysterectomy. ► Patient information: A handout on chronic pelvic pain, written by the author of this article, is provided on page 1544.

Chronic pelvic pain is defined in a variety of ways. A useful clinical definition of chronic pelvic pain is noncyclic pain that lasts six months or more; is localized to the pelvis, the anterior abdominal wall at or below the umbilicus, or the buttocks; and is of sufficient severity to cause functional disability or require medical care. Other definitions do not require that the pain be noncyclic.

Because the definition of chronic pelvic pain varies, it is difficult to ascertain its exact prevalence. In the United Kingdom, 3.8 percent of women in the primary care population report experiencing chronic pelvic pain, defined as noncyclic pain in the lower abdominal region lasting six months or more and without a specific disease diagnosis. This is similar to the prevalence of migraine headaches, asthma, and low back pain in the United Kingdom. However, in a 1996 study conducted in the United States, 15 percent of women indicated they had experienced either constant or intermittent pelvic pain during the preceding six months, which met the study’s criteria for chronic pelvic pain. The same study estimated the cost of outpatient medical visits associated with chronic pelvic pain to be $880 million per year in the United States, with 15 percent of women with chronic pelvic pain reporting lost time from paid work, and 45 percent reporting decreased productivity at work.

Etiology

The pathophysiology of chronic pelvic pain is not well understood. A definitive diagnosis is not made for 61 percent of women with chronic pelvic pain. Many patients and physicians incorrectly assume that all chronic pelvic pain results from a gynecologic source. One study in the United Kingdom found that diagnoses related to the urinary and gastrointestinal systems were more common than gynecologic diagnoses. Table 1 lists the more commonly diagnosed conditions that cause chronic pelvic pain.

The four most commonly diagnosed etiologies are endometriosis, adhesions, irritable bowel syndrome (IBS), and interstitial cystitis.
When evaluating a patient with chronic pelvic pain, the history and physical examination can narrow the differential diagnosis and guide further laboratory and ancillary testing. As many as 40 percent of women who present to primary care practices with chronic pelvic pain have more than one diagnosis. Therefore, it is important to investigate all contributing factors related to the pain including psychological, social, and environmental.\(^6\)\(^,\)\(^9\)\(^-\)\(^11\)

Women with chronic pelvic pain usually want the following: to receive personalized care from their physicians; to be taken seriously; to receive an explanation for their condition (more so than a cure); and to be reassured.\(^12\) Therefore, the physician should schedule several visits to complete the evaluation and provide appropriate counseling. **Table 2** contains a summary of selected findings on the history, physical examination, and diagnostic tests and their potential significance for the patient. The International Pelvic Pain Society has many helpful resources including history and physical examination forms (available at http://www.pelvicpain.org/resources/handpform.aspx), and patient education materials.

### History

The history should focus on characteristics of the pain, including quality, duration, and modifying factors, as well as its association with menses, sexual activity, urination, defecation, and radiation treatment.\(^13\) Because a history of physical or sexual abuse is associated with chronic pelvic pain, physicians should ask questions to address these two issues and assess current safety.\(^14\) Red flag symptoms, such as unexplained weight loss,

hematochezia, perimenopausal irregular bleeding, postmenopausal vaginal bleeding, or postcoital bleeding, should prompt an investigation to rule out malignancy or serious systemic disease. As with other chronic and painful conditions, depression may be a coexisting diagnosis.

Historical patterns may also help direct the work-up. Pain associated with hormonal changes may likely result from endometriosis or adenomyosis, while a nonhormonal pattern of pain may signal musculoskeletal causes, adhesions, IBS, or interstitial cystitis. However, hormonal patterns should be interpreted cautiously because pain caused by IBS and interstitial cystitis may also fluctuate based on hormone levels. A history of pelvic surgery, pelvic infections, or use of an intrauterine device should raise concern for pelvic adhesions.

**PHYSICAL EXAMINATION**

The physical examination can identify areas of tenderness and the presence of masses or other anatomical findings that aid in the diagnosis. However, a lack of findings during the physical examination does not rule out intra-abdominal pathology because many patients with a normal examination will have pathologic findings on subsequent laparoscopy.

The physical examination should proceed slowly and gently because both the abdominal and pelvic components of the examination may be painful. Palpation of the outer pelvis and back may reveal trigger points that indicate a myofascial component to the pain. The pelvic examination should begin with a single-digit, one-handed examination. A moistened cotton swab should be used to elicit point tenderness in the vulva.
Pelvic Pain

and vagina. The patient should be checked for any nodules, masses, or point tenderness along the bladder or other musculoskeletal structures. Once the single-digit, one-handed examination is completed, a bimanual examination should be performed to check again for nodularity, point tenderness, cervical motion tenderness, or lack of mobility of the uterus. A rectal examination may show rectal or posterior uterine masses, nodularity, or pelvic floor point tenderness.

Testing for Carnett’s sign should be performed by placing a finger on the painful, tender area of the patient’s abdomen and having the patient raise both legs off the table while lying in the supine position (Figure 1). A positive test occurs when the pain increases during this maneuver and is associated with a myofascial cause of the pain. This may also indicate that the cause of the pain is within the abdominal wall (e.g., fibromyalgia or trigger point). Visceral pain should not worsen during the maneuver.17

LABORATORY/SPECIALIZED TESTS

If the history and physical examination do not lead to a diagnosis, then cancer screenings appropriate to the patient’s age and associated risk factors should be performed. It may be appropriate to obtain a serum beta subunit of human chorionic gonadotropin (β-hCG) level to rule out pregnancy; a complete blood count; a urinalysis and urine culture; an erythrocyte sedimentation rate; and vaginal swabs to test for gonorrhea and chlamydia.19 Transvaginal ultrasound is also useful during the initial evaluation to investigate any pelvic masses or nodules found during the physical examination and to reassure the patient if no significant abnormalities are discovered.4,18

Magnetic resonance imaging and computed tomography should not be used routinely, but can help assess any abnormalities found on ultrasound.19 Some urologists use the intravesical potassium sensitivity test to help diagnose interstitial cystitis.20 Laparoscopy is often used when the diagnosis remains elusive after the initial workup or to confirm, and possibly treat, suspected endometriosis, adhesions, or both.7

Treatment

Few randomized controlled trials have studied the treatment of chronic pelvic pain. Because different definitions of chronic pelvic pain were used in some of these studies, many treatment recommendations are based on expert opinion or cohort/observational studies.

Treatment should be directed at the underlying cause of the pelvic pain. Figure 2 shows a suggested algorithm for the evaluation and management of patients with chronic pelvic pain.4,6,18,21-23 In patients for whom a specific diagnosis is not made, a multidisciplinary approach (i.e., addressing dietary, social, environmental, and psychological factors in addition to standard medication therapy) has been shown to improve outcomes over medication therapy alone.4 Table 3 lists specific details and references regarding the most common medication treatment options.1,4,6,21,22,24,25

A recent Cochrane analysis of treatments for chronic pelvic pain found that only the following treatments have shown benefit: oral medroxyprogesterone acetate (Provera), 50 mg daily; goserelin (Zoladex), an injectable gonadotropin-releasing hormone (GnRH) agonist; a multidisciplinary approach; counseling after a negative

Figure 1. Carnett’s sign for patients with pelvic pain. The examiner places his or her finger on the tender area of the patient’s abdomen and asks the patient to raise both legs off the table. An increase in the patient’s pain during this maneuver is considered a positive test.
Evaluation and Treatment of Chronic Pelvic Pain in Women

*—Warning signs include: unexplained weight loss, hematochezia, perimenopausal irregular or postmenopausal vaginal bleeding, or postcoital bleeding.
†—Consider referral for consultation or specific testing (e.g., laparoscopy) at any step of evaluation or treatment if the clinical picture is unclear, the patient does not respond to treatment as expected, or if significant underlying disease is suspected. This approach is only suggested as a stepwise process and should be individualized for each patient.

Figure 2. Algorithm for the evaluation and treatment of chronic pelvic pain in women presenting to primary care. (β-hCG = beta subunit of human chorionic gonadotropin; NSAIDs = nonsteroidal anti-inflammatory drugs.)

Information from references 1, 4, 6, 18, and 21 through 23.
ultrasound; and lysis of deep adhesions.4 Lysis of adhesions is only beneficial for more severe cases. This Cochrane review excluded patients with known endometriosis, IBS, primary dysmenorrhea, and chronic, active pelvic inflammatory disease, as these disease populations have slightly different therapeutic options than the larger population of patients with chronic pelvic pain.4

For pain that appears to be cyclic in nature, hormonal treatments (continuous or cyclic low-dose oral contraceptive pills, progestins, or GnRH agonists) should be considered, even if the cause is thought to be IBS, interstitial cystitis, or pelvic congestion syndrome, because these conditions may also respond to hormone treatments.1,4,21,22 Specific management of IBS, endometriosis, and interstitial cystitis has been described elsewhere.13,26,27

Although selective serotonin reuptake inhibitors have not been shown to be effective for treating chronic pelvic pain,4 they may be used to treat concomitant depression. These medications are used in the treatment of dysmenorrhea, and lysis of deep adhesions.

GnRH = gonadotropin-releasing hormone; IM = intramuscularly; NSAIDs = nonsteroidal anti-inflammatory drugs. Information from references 1, 4, 6, 21, 22, 24, and 25.

Trigger point injections of the abdominal wall for myofascial causes of chronic pelvic pain have also shown some benefit.28,29

ANALGESICS

Oral analgesics, such as acetaminophen, nonsteroidal anti-inflammatory drugs (NSAIDs), and opioid analgesics, are commonly used to treat moderate pain; however, there are no prospective controlled studies that show a specific benefit in chronic pelvic pain.1 If opioid analgesics are necessary to control pain, long-acting opioids with scheduled dosing may be used in conjunction with a treatment plan similar to that used when treating other chronic, painful conditions.4 Vitamin B6 and oral magnesium have been shown to benefit patients with dysmenorrhea, but there are no trials that evaluated their effectiveness for non-menstrual-related pain.30 A recent randomized, controlled, open-label study showed that gabapentin (Neurontin), alone or in combination with amitriptyline, provided
significant pain relief in women with chronic pelvic pain.\textsuperscript{3,4} Botulinum toxin type A injections into the pelvic floor muscles have also shown benefit.\textsuperscript{31,32}

**SURGICAL AND NERVE STIMULATION THERAPIES**

Among surgical therapies, only lysis of severe adhesions has been shown to benefit patients with chronic pelvic pain.\textsuperscript{4} Total abdominal hysterectomy showed some benefit in observational and cohort studies.\textsuperscript{33,34} Presacral neurectomy, along with ablative therapy for endometriosis, has shown benefit in the treatment of dysmenorrhea that is centrally located in the pelvis,\textsuperscript{35} but this finding cannot be generalized to chronic pelvic pain.

Several other therapies using the neuro-modulation theory of treating pain have been evaluated in patients with chronic pelvic pain. Uncontrolled studies of sacral nerve stimulation in women with chronic pelvic pain have shown some benefit.\textsuperscript{36,37} Two trials have shown some benefit in using percutaneous tibial nerve stimulation to treat chronic pelvic pain,\textsuperscript{38,39} although there are no large, placebo-controlled studies that confirm these findings.

**Referral**

Family physicians should consider referring patients with chronic pelvic pain for diagnostic procedures (e.g., laparoscopy, colonoscopy, cystoscopy), for therapeutic options (e.g., surgery or GnRH agonist treatment) that are beyond their scope of care, or if the underlying diagnosis and best treatment option are unclear. By performing a thorough initial work-up and knowing the local subspecialty practice scope and patterns, family physicians should be able to select the specific test or specialty (e.g., gynecology, urology, gastroenterology or pain management) in their community that would best provide the information and care that the patient requires. Because a multidisciplinary treatment approach will benefit most patients with chronic pelvic pain,\textsuperscript{4} the referring family physician should stay engaged in the care of the patient and coordinate the plan of care with any subspecialists involved.
