Vitamin D Supplementation in Infants, Children, and Adolescents

CATHERINE F. CASEY, MD; DAVID C. SLAWSON, MD; and LINDSEY R. NEAL, MD
University of Virginia Medical Center, Charlottesville, Virginia

Vitamin D deficiency in children can have adverse health consequences, such as growth failure and rickets. In 2008, the American Academy of Pediatrics increased its recommended daily intake of vitamin D in infants, children, and adolescents to 400 IU. Infants who are breastfed and children and adolescents who consume less than 1 L of vitamin D–fortified milk per day will likely need supplementation to reach 400 IU of vitamin D per day. This recommendation is based on expert opinion and recent clinical trials measuring biomarkers of vitamin D status. It is also based on the precedent of preventing and treating rickets with 400 IU of vitamin D. In addition to dietary sources, exposure to ultraviolet B sunlight provides children and adults with additional vitamin D. Although the American Academy of Pediatrics recommends keeping infants out of direct sunlight, decreased sunlight exposure may increase children's risk of vitamin D deficiency. No randomized controlled trials assessing patient-oriented outcomes have been performed on universal vitamin D supplementation. However, vitamin D may reduce the risk of certain infections and chronic diseases. Physicians should help parents choose the appropriate vitamin D supplement for their child. (Am Fam Physician. 2010;81(6):745-748, 750. Copyright © 2010 American Academy of Family Physicians.)

Adequate levels of vitamin D may also help reduce the risk of autoimmune conditions,4,5 infection,5 and type 2 diabetes.6 Evidence from observational studies supports the role of vitamin D supplementation in reducing the risk of type 1 diabetes in infants and children.7 Although observational studies suggest that vitamin D may be protective against some cancers,8 a randomized controlled trial of calcium and vitamin D supplementation in 36,282 women did not find a protective effect against breast cancer.9

Guidelines for Vitamin D Intake

In 2003, the American Academy of Pediatrics (AAP) published a guideline recommending that all children older than two months receive 200 IU of supplemental vitamin D daily.10 This expert consensus statement was supported by studies of breastfed infants in the United States, Norway, and China and suggested that infants who ingest 100 or 200 IU of supplemental vitamin D daily were less likely to develop rickets.11 Since then, there have been concerns that these dosages may be insufficient. These concerns are supported by studies showing that vitamin D deficiency can occur early in life;2 that serum 25-hydroxyvitamin D concentrations...
Vitamin D and Sunlight

In addition to dietary sources, children and adults obtain vitamin D through exposure to ultraviolet B sunlight. As little as 10 to 15 minutes of direct sunlight can generate 10,000 to 20,000 IU of vitamin D. Many factors influence vitamin D synthesis, such as skin pigmentation, latitude, and amount of skin exposed, making it difficult to assess how much vitamin D will be converted from sunlight exposure. Infants and children who have darker pigmentation require five to 10 times the length of sunlight exposure to reach the same levels of 25-hydroxyvitamin D when compared with children who have lighter pigmentation.23 However, the AAP recommends that infants younger than six months be kept out of direct sunlight.24 Although the goal of limiting sunlight exposure is to minimize the risk of skin cancer, it may also predispose children to vitamin D deficiency.25-27 Because the safe level of sunlight exposure needed for vitamin D conversion is unknown, increasing vitamin D supplementation is a reasonable alternative.

Complications of Vitamin D Deficiency

Risk factors for vitamin D deficiency are summarized in Table 1. Physicians should confirm suspicion of vitamin D deficiency by measuring levels of 25-hydroxyvitamin D, which is the best available biomarker for checking vitamin D status.28,29 Vitamin D deficiency in adults is defined as 25-hydroxyvitamin D levels of less than 20 ng per mL (50 nmol per L), although this varies among studies.30 There is no set level of 25-hydroxyvitamin D to confirm vitamin D deficiency in infants, children, and adolescents. Although no set level has been established for children and adolescents, recent studies have used less than 15 to 20 ng per mL (37.44 to 50 nmol per L) as a cutoff for vitamin D deficiency in these age groups.

Patients with severe cases of rickets may present with growth failure, hypocalcemic seizures, decreased bone mass, and characteristic bone changes or fractures (Figure 1). Nonspecific symptoms, such as irritability, lethargy, and developmental delay, may be less obvious. In a case-control study of children hospitalized for acute illnesses, investigators found an increased rate of admissions for lower respiratory tract infections among those with rickets.31

Supplementation Options

Vitamin D₃, known as cholecalciferol, is the preferred form of vitamin D for supplementation. Children with certain conditions, such as fat malabsorption, and those who require long-term use of seizure medications may need higher dosages of vitamin D because of increased risk of deficiency.32-34 Monitoring 25-hydroxyvitamin D levels every three months, and parathyroid hormone levels and bone-mineral status every six months, is recommended for these children.

Vitamin D deficiency during pregnancy may increase the risk of abnormal fetal growth and bone development, but further studies are needed before high-dose supplementation in pregnant women can be universally recommended.35

No evidence suggests that daily supplementation of 400 IU of vitamin D is toxic. Physicians should provide patients with detailed administration instructions to avoid accidental overdose. Vitamin D₃ drops, which are preferable for infants, are available in formulations of 400, 1,000, and 2,000 IU per drop. Varying amounts of vitamin D₃ are available within formulations of the same brand. Chewable and gummy vitamins for older children contain 200 or 400 IU of vitamin D₃, but may vary by formulation from the same manufacturer. Physicians may prefer to recommend one brand and formulation for each age group to ensure that patients reach a daily dosage of 400 IU (Tables 2 and 3).

The Authors
