Treatment Options for Localized Prostate Cancer

RAVINDER MOHAN, MD, PhD, and PAUL F. SCHELLHAMMER, MD
Eastern Virginia Medical School, Norfolk, Virginia

In the United States, more than 90 percent of prostate cancers are detected by serum prostate-specific antigen testing. Most patients are found to have localized prostate cancer, and most of these patients undergo surgery or radiotherapy. However, many patients have low-risk cancer and can follow an active surveillance protocol instead of undergoing invasive treatments. Active surveillance is a new concept in which low-risk patients are closely followed and proceed to intervention only if their cancer progresses. Clinical guidelines can help in selecting between treatment or active surveillance based on the cancer’s stage and grade, the patient’s prostate-specific antigen level, and the comorbidity-adjusted life expectancy. Radical prostatectomy or external beam radiation therapy is recommended for higher-risk patients. These treatments are almost equivalent in effectiveness, but have different adverse effect profiles. Brachytherapy is an option for low- and moderate-risk patients. Evidence is insufficient to determine whether laparoscopic or robotic surgery or cryotherapy is superior to open radical prostatectomy. (Am Fam Physician. 2011;84(4):413-420. Copyright © 2011 American Academy of Family Physicians.)

Patient information:
A handout on treatment options for prostate cancer, written by the authors of this article, is provided on page 424.
effects on health-related quality of life, about 70 to 90 percent of patients choose a treatment during the first visit to a urologist after a positive biopsy. In a survey of 184 men with newly diagnosed prostate cancer, more than one-half significantly overestimated the survival benefit of treatment. Education, income, and health literacy did not affect the results; 60 percent of the survey respondents were college educated and had an annual income more than $50,000, and more than 90 percent had at least a ninth-grade health literacy.

Although these patients had been counseled by their urologists and had already elected treatment or observation, more than 50 percent incorrectly answered more than one-half of the 18 items in a questionnaire designed to test their knowledge, understanding, and judgment about the advantages and disadvantages of different treatment options for prostate cancer. This questionnaire can be used to identify patients who need further counseling about treatment choices (Figure 1).

With the help of clinical guidelines, primary care physicians can counsel patients in choosing a treatment or observation. Guidelines from the National Comprehensive Cancer Network (NCCN), American Cancer Society, and American Urological Association are available at http://www.nccn.org/professionals/physician_gls/PDF/prostate.pdf (registration required), http://www.psa-rising.com/download/nccnguidelines.pdf, and http://www.auanet.org/content/guidelines-and-quality-care/clinical-guidelines/main-reports/proscan07/content.pdf. The NCCN guidelines are based on high-level evidence or uniform consensus. The American Urological Association guideline provides useful data on the advantages and disadvantages of different treatment options. An algorithm based on the NCCN guideline is presented in Figure 2.

### Diagnosis

The most recent guideline from the American Cancer Society recommends transrectal ultrasonography-guided prostate biopsy as a reasonable option in men with PSA levels of 4 ng per mL (4 mcg per L) or greater. Biopsy may also be reasonable in men with PSA levels of 2.5 to 4.0 ng per mL (2.5 to 4.0 mcg per L) and who have risk factors for prostate cancer. Other relative indications for biopsy include PSA levels that are higher than age-adjusted ranges; less than 8 percent free PSA (versus total PSA); and an increase in PSA levels of more than 0.35 ng per mL (0.35 mcg per L) in one year in patients with a baseline level of less than 4 ng per mL, or an increase of more than 0.75 ng per mL (0.75 mcg per L) in one year in patients with a baseline level of 4 to 10 ng per mL (4 to 10 mcg per L). Taking 12 biopsy cores is recommended; this may detect 31 percent more cancers than the traditional six biopsy cores, without an increase in adverse effects.

### Treatment

The NCCN guidelines use four factors in determining the recommended treatment: the stage and grade of the cancer, the patient’s PSA level, and the estimated baseline life expectancy of the patient.
### Knowledge, Understanding, and Judgment Questionnaire

Use this questionnaire if a biopsy has shown that you have localized prostate cancer. These questions will assess how well you understand your treatment options. Choose only one answer for each question.

**1. The stage of your cancer is:**
- [ ] Stage 1 (very early; has not spread).
- [ ] Stage 2 (early; has spread within the prostate).
- [ ] Stage 3 (has spread outside the prostate).
- [ ] Stage 4 (has spread throughout the body).

**2. The grade, or aggressiveness, of your cancer is:**
- [ ] Very slow growing.
- [ ] Slow growing.
- [ ] Average.
- [ ] Fast growing.
- [ ] Very fast growing.

**3. Your prostate-specific antigen (PSA) level is:**
- [ ] Less than 5 ng per mL (5 mcg per L).
- [ ] 5 to less than 10 ng per mL (5 to less than 10 mcg per L).
- [ ] 10 to 50 ng per mL (10 to 50 mcg per L).
- [ ] More than 50 ng per mL (50 mcg per L).

**4. After surgery, the most common complication is:**
- [ ] Pain on urination.
- [ ] Urine leakage.
- [ ] Diarrhea.
- [ ] Impotence.
- [ ] None of these.

**5. After radiation therapy, the most common complication is:**
- [ ] Pain on urination.
- [ ] Urine leakage.
- [ ] Diarrhea.
- [ ] Impotence.
- [ ] None of these.

**6. Without treatment, the most common complication of prostate cancer is:**
- Pain on urination.
- Urine leakage.
- Diarrhea.
- Impotence.
- None of these.

**7. Without treatment, more than one-half of men with prostate cancer will have sexual or urinary problems within five years.**
- [ ] True
- [ ] False

**8. One out of three patients who have surgery will have some bladder control problems after surgery.**
- [ ] True
- [ ] False

**9. One out of three patients who have surgery will need to wear diapers because of bladder control problems.**
- [ ] True
- [ ] False

**10. One out of 10 patients who have surgery will need to wear diapers because of bladder control problems.**
- [ ] True
- [ ] False

**11. Three out of four patients will have erections firm enough to have sexual intercourse after prostate surgery.**
- [ ] True
- [ ] False

**12. Four out of five patients who get radiation rays (not seeds) are able to have erections firm enough to have intercourse after treatment.**
- [ ] True
- [ ] False

**13. Four out of five patients who get radiation seeds are able to have erections firm enough to have intercourse after treatment.**
- [ ] True
- [ ] False

**14. Without treatment, at least one out of three patients will die from prostate cancer within 10 years.**
- [ ] True
- [ ] False

**15. You should make a decision about which treatment you choose within six months, or the cancer can spread beyond cure.**
- [ ] True
- [ ] False

**16. Without treatment, prostate cancer will spread in one out of three patients within 10 years.**
- [ ] True
- [ ] False

**17. Keeping in mind your age and current health, how much longer do you expect to live if your prostate cancer is not treated?**
- [ ] Less than five years.
- [ ] Less than 10 years.
- [ ] Less than 20 years.
- [ ] 20 years or more.

**18. Keeping in mind your age and current health, how much longer do you expect to live if your prostate cancer is treated?**
- [ ] Less than five years.
- [ ] Less than 10 years.
- [ ] Less than 20 years.
- [ ] 20 years or more.

---

**SCORING:** For questions 1 to 3, the correct answer is the known stage and grade of cancer, and the most recent PSA level. Correct answers for the remaining questions are as follows: 4, impotence; 5, impotence; 6, none; 7, false; 8, true; 9, false; 10, true; 11, false; 12, false; 13, true; 14, false; 15, false; 16, true. For questions 17 and 18, a comparison of responses with the baseline life expectancy can assess whether survival expectations (related to the cancer and its treatment) are realistic.

**Figure 1.** Knowledge, Understanding, and Judgment Questionnaire used to identify patients who need further counseling about treatment options for prostate cancer.

Adapted with permission from Beydoun HA, Mohan R, Beydoun MA, Davis J, Lance R, Schellhammer P. Development of a scale to assess patient misperceptions about treatment choices for localized prostate cancer. BJU Int. 2010;106(3):336.
CANCER STAGE
Stages T1 (not palpable) and T2 (palpable but limited to the prostate) are considered localized if there are no lymph nodes involved and no distant metastasis.

CANCER GRADE AND OTHER HISTOLOGIC FINDINGS
The Gleason score is determined by adding the grades of the two most common histologic patterns seen in each biopsy core. Each pattern is scored from 1 to 5, with 5 being most poorly differentiated. For example, if grade 3 is the most common pattern and grade 4 is the next most common pattern, the Gleason score would be 7 (3+4). The most common grade is 6, whereas grades 2 to 5 are uncommon. Grade 6 identifies a tumor with well-differentiated histology; grade 7 has intermediate differentiation; and grades 8 to 10 are the most poorly differentiated and have the worst prognosis. A grade 7 cancer is more aggressive if its scoring is 4+3 instead of 3+4.

Figure 2. Algorithm based on a guideline from the National Comprehensive Cancer Network for selection of treatment for localized prostate cancer. (CALE = comorbidity-adjusted life expectancy; EBRT = external beam radiation therapy; PSA = prostate-specific antigen; RP = radical prostatectomy.)
Information from reference 17.
PSA LEVEL

PSA levels of 4 to less than 10 ng per mL, 10 to 20 ng per mL (10 to 20 mcg per L), and greater than 20 ng per mL are associated with a low, intermediate, and high risk of prostate cancer recurrence after treatment, respectively.

COMORBIDITY-ADJUSTED LIFE EXPECTANCY

This factor is particularly important because the number of comorbid diseases is the most significant predictor of survival after treatment of prostate cancer. Prostate cancer is usually slow growing, and the survival benefit of treatment may present only after 10 years or longer. This is the basis of the “10-year rule”: a patient with prostate cancer should be treated only if the patient has a comorbidity-adjusted life expectancy of at least 10 years. Age alone is not accurate in estimating life expectancy. To estimate comorbidity-adjusted life expectancy, the NCCN recommends the use of health status quartiles that match corresponding quartiles of life expectancy at each year of age. Tables 1a and 1b give a short patient-administered Charlson Comorbidity Index for a quick estimation of comorbidity-adjusted life expectancy.

Comparison of Treatment Choices

A systematic review did not find any good-quality head-to-head trials comparing radical prostatectomy with radiotherapy. Many trials studied biochemical progression but

not long-term survival, and some trials were conducted before the advent of PSA testing. No trial has compared treatment outcomes by race or ethnicity, and most trials do not provide baseline racial characteristics.

**SURGERY**

Among patients in whom cancer was detected clinically (not by PSA screening), those who underwent radical prostatectomy (RP) had fewer prostate cancer–related deaths than patients who chose watchful waiting, although this benefit was limited to patients younger than 65 years.\(^{25}\) Patients who were operated on by surgeons who performed more than 40 RPs per year had fewer urinary adverse effects. Laparoscopic RP performed with or without the use of robotic technology is associated with less blood loss and shorter hospital stays, but all long-term outcomes are similar to open RP. In robotic laparoscopic RP, surgeons with more experience were more likely to achieve complete resection of the cancer.\(^{25}\)

**EXTERNAL BEAM RADIATION THERAPY**

A systematic review found that surgery and external beam radiation therapy (EBRT) were equivalent in effectiveness, especially if the baseline PSA level was greater than 10 ng per mL.\(^{25}\) EBRT is given over eight to nine weeks and is associated with more bowel adverse effects than surgery. Surgery is more difficult if cancer recurs after EBRT. The review found one trial in which proton therapy was more effective than EBRT.\(^{25}\)

**BRACHYTHERAPY**

In patients with low-risk cancer, brachytherapy using iodine-125 or palladium-103 pellet implantation is recommended as monotherapy.\(^{17}\) It is a preferred option in these patients because it controls the cancer as effectively as surgery or EBRT, and patients experience much less urinary incontinence and erectile dysfunction. Implantation may be difficult in patients who have bladder outlet obstruction or a very large or very small prostate, and in those who have had previous prostate surgery.

**OTHER TREATMENT OPTIONS**

Hormone therapy (also known as androgen deprivation therapy) as an adjunct to surgical treatment is discouraged in low-risk patients because it does not increase treatment effectiveness and is associated with gynecomastia and erectile dysfunction.\(^{17,25}\) Cryotherapy and high-frequency ultrasound are not recommended as routine monotherapies.

**Adverse Effects**

Adverse effects vary depending on the treatment modality used; the specialist’s experience; the criteria used to assess the frequency, severity, and duration of symptoms and their baseline status; and the medications or devices used to treat the symptoms. Table 2 shows the incidence of adverse effects two years after surgery and EBRT.\(^{26}\) Adverse effects noted five years after treatment include no urinary control or frequent urinary leakage (14 percent
after surgery versus 5 percent after EBRT, with pad use in 29 percent of surgical patients and 4 percent of EBRT patients.\textsuperscript{25} After adjusting for baseline factors, dripping or leaking urine was noted six times more often after surgery than after EBRT.\textsuperscript{25} Erections insufficient for intercourse occurred in approximately three-fourths of patients after surgery or EBRT.\textsuperscript{25} Despite these adverse effects, less than 5 percent of patients reported dissatisfaction with treatment, and more than 90 percent of patients said they would make the same decision again.\textsuperscript{25} Patients who underwent surgery were most satisfied. Patient satisfaction was highly related with adverse effects, but also with the perception of freedom from prostate cancer.

**Active Surveillance**

Compared with observation and watchful waiting, active surveillance is a more structured program to track the progression of prostate cancer, allowing for earlier intervention if the patient’s risk is found to increase on follow-up. A protocol used in Canada is shown in Table 3; with the use of this protocol, patient survival is similar to that after treatment (99.2 percent at eight years in 299 patients).\textsuperscript{9} About 25 percent of patients in this protocol proceed to intervention.\textsuperscript{9} Patient survival in a European study was 100 percent at 10 years in 616 patients.\textsuperscript{27} In this ongoing study, patients continue with active surveillance only if their PSA level (checked every three months) doubles in more than three years; if cancer is present in only one or two biopsy cores; and if their Gleason score remains 6 (3+3) or lower (biopsy is done if the PSA doubling time is three to 10 years, and routinely at one, three, five, and seven years, then every five years thereafter). Active surveillance is recommended for low- and very low-risk patients. Drawbacks include the potentially increased difficulty of curative or nerve-sparing surgery in patients for whom intervention is delayed despite increasing risk, and mild anxiety. However, men following this protocol have been found to have favorable levels of anxiety and distress.\textsuperscript{28}
