ACIP Updates Guideline on Influenza Vaccination for 2012-2013 Season
GENEVIEVE RESSEL

The Advisory Committee on Immunization Practices (ACIP) of the Centers for Disease Control and Prevention (CDC) has issued its annual guideline on influenza vaccination. This year’s guideline provides information on dosing considerations for children six months to eight years of age, febrile seizures associated with trivalent inactivated vaccine (TIV) and the 13-valent pneumococcal conjugate vaccine (PCV13), and vaccination of persons allergic to eggs.

The 2012-2013 seasonal influenza vaccine contains A/California/7/2009 (H1N1)-like, A/Victoria/361/2011 (H3N2)-like, and B/Wisconsin/1/2010-like (Yamagata lineage) antigens, which differ from the 2011-2012 vaccine. The influenza A (H1N1) vaccine virus strain is derived from an influenza A (H1N1)pdm09 (2009[H1N1]) virus and was included in the 2009(H1N1) monovalent pandemic vaccine, as well as the 2010-2011 and 2011-2012 seasonal vaccines.

To ensure full production of protective antibody levels before influenza activity begins, health care professionals should provide vaccination as soon as the vaccine is available. Annual vaccination is recommended for all persons six months and older. Table 1 lists the vaccines available for the 2012-2013 influenza season.

Updates

VACCINATION IN CHILDREN SIX MONTHS TO EIGHT YEARS OF AGE

Children six months to eight years of age need two doses of vaccine, administered at least four weeks apart, during their first season for vaccination. For children who last received seasonal influenza vaccine before the 2010-2011 season but did not receive a vaccine containing 2009(H1N1) antigen (i.e., seasonal vaccine since July 2010 or monovalent 2009[H1N1] vaccine), it is recommended that they receive two doses this season, even if they received two doses of seasonal vaccine before the 2010-2011 influenza season (Figure 1). Children in this age group need only one dose of vaccine this year if they received two or more doses of seasonal vaccine since July 1, 2010; two or more doses of seasonal influenza vaccine before July 1, 2010, and one or more doses of monovalent 2009(H1N1) vaccine; or one or more doses of seasonal influenza vaccine before July 1, 2010, and one or more doses of seasonal influenza vaccine since July 1, 2010.

FEBRILE SEIZURES ASSOCIATED WITH TIV AND PCV13

After a report of increased risk of febrile seizure after influenza vaccination in Australia, the CDC and U.S. Food and Drug Administration enhanced monitoring during the 2010-2011 influenza season. In response to the findings in Australia, ACIP does not recommend Afluria for children younger than nine years. Increased risk for febrile seizure ▶

NOTE: Vaccination providers should consult U.S. Food and Drug Administration–approved prescribing information for 2012-2013 influenza vaccines for the most updated information, including indications, contraindications, and precautions.

LAIV = live-attenuated influenza vaccine; TIV = trivalent inactivated vaccine.

*—Data on maximum ovalbumin content is supplied in package inserts of certain vaccines. Persons with a history of mild allergy to egg (specifically, those who experience only hives) should receive TIV with additional precautions (Figure 2).

†—Information is not included in package insert but is available upon request from the manufacturer, Sanofi Pasteur, by contacting 1-800-822-2463 or mis.emails@sanofipasteur.com.

‡—Figure 1 describes two approaches for determining the number of doses needed for children six months to eight years of age.

§—For adults and older children, the recommended site of vaccination is the deltoid muscle. The preferred site for infants and young children is the anterolateral aspect of the thigh.

¶—Age indication per package insert is five years and older; however, the Advisory Committee on Immunization Practices recommends that Afluria not be used in children six months to eight years of age because of increased risk for febrile reactions noted in this age group with CSL’s 2010 Southern Hemisphere TIV. If no other age-appropriate, licensed inactivated seasonal influenza vaccine is available for a child five to eight years of age who has a medical condition that increases the child’s risk of influenza complications, Afluria can be used; however, vaccination providers should discuss with the parents or caregivers the benefits and risks of influenza vaccination with Afluria before administering this vaccine. Afluria may be used in persons nine years and older.

‖—A 0.5-mL dose contains 60 mcg of each vaccine antigen (180 mcg total).

**—A 0.1-mL dose contains 9 mcg of each vaccine antigen (27 mcg total).

††—A new quadrivalent formulation of Flumist was approved by the U.S. Food and Drug Administration in February 2012. It is anticipated that this formulation will replace the currently available seasonal trivalent LAIV formulation for the 2013-2014 season. Flumist is shipped refrigerated and stored in the refrigerator at 35°F to 46°F (2°C to 8°C) after arrival in the vaccination clinic. The dose is 0.2 mL divided equally between each nostril. Health care professionals should consult the medical record, when available, to identify children two to four years of age with asthma or recurrent wheezing that might indicate asthma. In addition, to identify children who might be at greater risk for asthma and possibly at increased risk for wheezing, vaccination providers should discuss with the parents or caregivers the benefits and risks of influenza vaccination with Afluria before administering this vaccine. Afluria may be used in persons nine years and older.

††—Insufficient data available for use of LAIV in persons allergic to eggs.

§§—Flumist is indicated for healthy, nonpregnant persons two to 49 years of age. Persons who care for severely immunosuppressed persons who require a protective environment should not receive Flumist because of the theoretical risk of transmission of the live-attenuated vaccine virus.

Influenza Vaccination Dosing in Children Six Months to Eight Years of Age

Has the child ever received influenza vaccine?

Yes

Did the child receive a total of two or more doses of seasonal influenza vaccine since July 1, 2010?

Yes

One dose

No/Do not know Two doses*†

No

Two doses*†

*—Doses should be administered at least four weeks apart.
†—For simplicity, this algorithm takes into consideration only doses of seasonal influenza vaccine received since July 1, 2010. As an alternative approach in settings where vaccination history from before July 1, 2010, is available, a child six months to eight years of age is known to have received at least two seasonal influenza vaccines during any previous season, and at least one dose of a 2009(H1N1)-containing vaccine (i.e., 2010-2011 or 2011-2012 seasonal vaccine or the monovalent 2009[H1N1] vaccine), then the child needs only one dose for 2012-2013. Using this approach, children six months to eight years of age need only one dose of vaccine in 2012-2013 if they have received any of the following: (1) two or more doses of seasonal influenza vaccine since July 1, 2010; (2) two or more doses of seasonal influenza vaccine before July 1, 2010, and one or more doses of monovalent 2009(H1N1) vaccine; or (3) one or more doses of seasonal influenza vaccine before July 1, 2010, and one or more doses of seasonal influenza vaccine since July 1, 2010. Children for whom one of these conditions is not met require two doses in 2012-2013.

Influenza Vaccination in Patients with Egg Allergy

Can the person eat lightly cooked egg (e.g., scrambled egg) without reaction?*

Yes

Administer vaccine per usual protocol

No

After eating eggs or egg-containing foods, does the person experience only hives?

Yes

Administer trivalent inactivated vaccine

Observe for reaction for at least 30 minutes after vaccination

No

Does the person experience other symptoms, such as:

Cardiovascular changes (e.g., hypotension)?

Respiratory distress (e.g., wheezing)?

Gastrointestinal symptoms (e.g., nausea or vomiting)?

Reaction requiring epinephrine?

Reaction requiring emergency medical attention?

Yes

Refer to a physician with expertise in management of allergic conditions for further evaluation

No

*—Persons with egg allergy might tolerate egg in baked products (e.g., bread or cake). Tolerance to egg-containing foods does not exclude the possibility of egg allergy.

Figure 1. Algorithm for influenza vaccine dosing in children six months to eight years of age.

VACCINATION IN PATIENTS WITH EGG ALLERGY

For patients with a history of egg allergy who have experienced only hives, ACIP recommends vaccination with TIV rather than live-attenuated influenza vaccine, that the vaccine be administered by a health care professional proficient in potential manifestations of egg allergy, and observation for at least 30 minutes after vaccination (Figure 2). Persons who have had reactions to egg proteins that include angioedema, respiratory distress, lightheadedness, or recurrent emesis, or who required epinephrine or other emergency medical intervention, are more likely to have a systemic or anaphylactic reaction to the vaccination. These patients should be referred to a physician with expertise in management of allergic reactions for further risk assessment. A previous severe reaction to the influenza vaccine is a contraindication to future vaccination.
