Sick Sinus Syndrome: A Review

MICHAEL SEMELKA, DO, and JEROME GERA, MD, Excela Health Latrobe Hospital, Latrobe, Pennsylvania
SAIF USMAN, MD, University of Missouri–Kansas City School of Medicine, Kansas City, Missouri

Sick sinus syndrome refers to a collection of disorders marked by the heart’s inability to perform its pacemaking function. Predominantly affecting older adults, sick sinus syndrome comprises various arrhythmias, including bradyarrhythmias with or without accompanying tachyarrhythmias. At least 50 percent of patients with sick sinus syndrome develop alternating bradycardia and tachycardia, also known as tachy-brady syndrome. Sick sinus syndrome results from intrinsic causes, or may be exacerbated or mimicked by extrinsic factors. Intrinsic causes include degenerative fibrosis, ion channel dysfunction, and remodeling of the sinoatrial node. Extrinsic factors can be pharmacologic, metabolic, or autonomic. Signs and symptoms are often subtle early on and become more obvious as the disease progresses. They are commonly related to end-organ hypoperfusion. Cerebral hypoperfusion is most common, with syncope or near-fainting occurring in about one-half of patients. Diagnosis may be challenging, and is ultimately made by electrocardiographic identification of the arrhythmia in conjunction with the presence of symptoms. If electrocardiography does not yield a diagnosis, inpatient telemetry monitoring, outpatient Holter monitoring, event monitoring, or loop monitoring may be used. Electrophysiologic studies also may be used but are not routinely needed. Treatment of sick sinus syndrome includes removing extrinsic factors, when possible, and pacemaker placement. Pacemakers do not reduce mortality, but they can decrease symptoms and improve quality of life. (Am Fam Physician. 2013;87(10):691-696. Copyright © 2013 American Academy of Family Physicians.)

Sick sinus syndrome is a collection of disorders defined by abnormal cardiac impulse formation and by abnormal propagation from the sinoatrial node, which prevents it from performing its pacemaking function. This condition, also known as sinus node dysfunction, is associated with an atrial rate that does not meet the body’s physiologic requirements. It manifests clinically as arrhythmias that can include sinus bradycardia, sinus pauses or arrest, sinoatrial exit block, or alternating bradyarrhythmias and tachyarrhythmias. These manifestations can lead to chronotropic incompetence, which is an inadequate heart rate response to exercise or stress.1-6

Prevalence
Sick sinus syndrome usually occurs in older adults, but it can affect persons of all ages. One in 600 cardiac patients older than 65 years has this syndrome.1 In one study of patients older than 21 years with sick sinus syndrome, the median age was 74 years.7 Men and women are affected equally.7

Causes
The etiology of sick sinus syndrome can be divided into intrinsic causes and extrinsic factors that disrupt the function of the sinoatrial node (Table 1).1,3,6,8-10

INTRINSIC CAUSES
Intrinsic causes of sick sinus syndrome include degenerative fibrosis of the sinoatrial node, ion channel dysfunction, and remodeling of the sinoatrial node. Historically, the most common intrinsic cause is thought to be age-related, idiopathic degenerative fibrosis of the sinoatrial node.6 Recent research and understanding of familial and congenital sick sinus syndromes, however, have shown that an inherited dysfunction of ion channels within the sinoatrial node also plays a significant part in age-related sick sinus syndrome.1,9,11-13

Remodeling of the sinoatrial node occurs in heart failure and atrial fibrillation, and this appears to play a role in the development of sick sinus syndrome for some patients.1,14,15 Certain infiltrative disease processes, including connective tissue diseases, hemochromatosis, sarcoidosis, and amyloidosis, may also cause intrinsic dysfunction of the sinoatrial node.10 Atherosclerotic changes of the sinus node artery, which originates from the proximal right coronary artery in 65 percent of patients,10 may contribute to chronic
Sick Sinus Syndrome

ischemia and subsequent fibrosis of the sinoatrial node, but are not considered to be a major cause of sick sinus syndrome.3,16

EXTRINSIC FACTORS

Extrinsic factors that can mimic or exacerbate sick sinus syndrome include the use of certain pharmacologic agents, metabolic disturbances, and autonomic dysfunction. The pharmacologic agents that commonly cause dysfunction of the sinoatrial node are beta blockers, calcium channel blockers, digoxin, sympatholytic medications, antiarrhythmic medications, and lithium.10,17 The most common electrolyte abnormalities leading to dysfunction of the sinoatrial node are hyperkalemia, hypokalemia, and hypocalcemia.

Other extrinsic factors include hypothyroidism, hypoxia, hypothermia, and toxins. Autonomic dysfunction can mimic or exacerbate sick sinus syndrome via neurally mediated bradycardia in vasovagal syncope, neurocardiogenic syncope, and carotid sinus hypersensitivity.10,18-20 Although rare, findings of sick sinus syndrome can be associated with other cardiac abnormalities such as Brugada syndrome, which is an ion channel disorder that can lead to sudden cardiac death.5,21

Signs and Symptoms

Sick sinus syndrome tends to be progressive. Patients often are asymptomatic early in the disease course, whereas those with more advanced disease can present with symptoms and signs of end-organ hypoperfusion. Cerebral hypoperfusion is the most common, and approximately 50 percent of patients with sick sinus syndrome have near-fainting spells or syncope.3,4,22 End-organ hypoperfusion can also manifest as transient lightheadedness, confusion, fatigue, palpitations, angina, congestive heart failure, stroke, transient ischemic attacks, vague gastrointestinal symptoms, or oliguria.3,4,22,23

Electrocardiographic Findings

The diagnosis of sick sinus syndrome requires electrocardiographic findings of bradyarrhythmias, such as sinus bradycardia, sinoatrial pause of three seconds or more, sinoatrial exit block, or sinus arrest (Table 2)\textsuperscript{3,24}. However, findings often are normal in patients with sick sinus syndrome, particularly early in the disease course, making the diagnosis a challenge.

Although bradyarrhythmias are required for the diagnosis, supraventricular tachyarrhythmias are present in at least 50 percent of patients with sick sinus syndrome\textsuperscript{6,25}. Episodes of alternating tachyarrhythmias and bradyarrhythmias are known as tachycardia-bradycardia, or tachy-brady, syndrome\textsuperscript{1,3,6,25} (Figure 1).

The most common tachyarrhythmias are atrial fibrillation or flutter with rapid ventricular response\textsuperscript{5,6}. These tachyarrhythmias are more common in older patients with advanced sinoatrial nodal disease in whom sinoatrial node fibrosis may favor reentrant beats or tachycardia\textsuperscript{8,26}. Additionally, there is evidence that atrial fibrillation and flutter can lead to atrial remodeling and subsequent dysfunction of the sinoatrial node\textsuperscript{3,14,15}.

Clinical Diagnosis

Sick sinus syndrome is diagnosed by correlating symptoms of end-organ hypoperfusion with the occurrence of bradycardia, with or without accompanying tachycardia\textsuperscript{3}. Electrocardiographic abnormalities and clinical symptoms must be present. Marked bradycardia, including sinoatrial pauses of three seconds or more, is not diagnostic of sick sinus syndrome in the absence of symptoms. Electrocardiographic abnormalities in the absence of symptoms may be explained by physiologic and pathophysiologic processes such as increased vagal tone during sleep or obstructive sleep apnea\textsuperscript{6,27,28}.

When 12-lead electrocardiography does not yield a diagnosis, prolonged cardiac monitoring should be considered\textsuperscript{5,29}. Depending on the severity of symptoms and the overall clinical picture, this can be done in the hospital via telemetry monitoring or on an outpatient basis with a 24- to 48-hour Holter monitor\textsuperscript{30}. If no definitive diagnosis is made, Holter monitoring can be repeated. If clinical suspicion of arrhythmia remains high and Holter monitoring results are negative, the next step should be longer-duration cardiac monitoring\textsuperscript{31-33}. Monitoring can occur for weeks at a time with external continuous or event monitors, or for months at a time with an implantable loop recorder; Table 3 lists available ambulatory monitoring devices\textsuperscript{30,34,35}.

Although rhythm monitoring is the diagnostic standard, electrophysiologic studies are sometimes useful in the evaluation of sick sinus syndrome. These studies evaluate patients in whom sick sinus syndrome is strongly suspected but no arrhythmia has been demonstrated that correlates with symptoms after prolonged cardiac monitoring\textsuperscript{7}.

The rhythm abnormalities of sick sinus syndrome occasionally are detected or suspected as an incidental finding during evaluation and treatment of other cardiac conditions\textsuperscript{36}. For example, two small studies of...
patients undergoing exercise treadmill testing found that 38 to 57 percent of patients with known sick sinus syndrome were unable to achieve a maximal heart rate of 120 beats per minute.\(^6\)\(^,\)\(^7\)\(^,\)\(^8\) This inadequate response to exercise suggests chronotropic incompetence that occurs in persons with sick sinus syndrome, but there are no well-validated standards for diagnosing sick sinus syndrome in this setting.\(^6\)

Carotid sinus massage or pressure that results in a sinoatrial pause for more than three seconds is also suggestive, but not diagnostic, of sick sinus syndrome.\(^3\)\(^,\)\(^5\)\(^,\)\(^18\)

### Complications of Sick Sinus Syndrome

More than 50 percent of patients with sick sinus syndrome develop tachy-brady syndrome with atrial fibrillation or flutter as the tachyarrhythmia, leading to an increased risk of embolic stroke. Anticoagulation therapy has been shown to decrease the number of embolic events and strokes, and the decision to start anticoagulant medication can be based on American College of Cardiology Foundation/American Heart Association guidelines.\(^39\)

Patients with sick sinus syndrome are also at risk of developing atrioventricular block. This occurs in 0.5 to 1.5 percent of patients per year,\(^6\)\(^,\)\(^40\) and eventually develops in as many as one-half of patients with sick sinus syndrome.\(^41\)

### Treatment

Permanent pacemaker placement is recommended only in patients with symptomatic sick sinus syndrome and documented bradycardia; it is the only effective treatment for chronic symptomatic sick sinus syndrome that is not caused by correctable extrinsic factors.\(^1\)\(^,\)\(^3\)\(^,\)\(^25\)

In 2009, there were 235,567 new pacemakers implanted in the United States.\(^42\) Historically, sick sinus syndrome accounts for one-half of pacemaker implantations.\(^1\)\(^,\)\(^3\)\(^,\)\(^25\)

Pacemaker therapy has not been shown to affect survival rates in this population. Rather, the primary goal of pacemaker placement is to relieve symptoms and

Implantation is indicated

Significant symptoms of bradycardia and documented heart rate less than 40 beats per minute without documentation of bradycardia during symptoms

Syncope of unexplained origin with dysfunction of sinoatrial node discovered or provoked in electrophysiologic studies

Implantation is reasonable

Minimally symptomatic patients with chronic heart rate less than 40 beats per minute while awake

Implantation may be considered

NOTE: The American College of Cardiology/American Heart Association/Heart Rhythm Society guidelines rated the supporting evidence for these recommendations as Level C (consensus, disease-oriented evidence, usual practice, expert opinion, or case series). Information from reference 6.

Table 5. Pacemaker Options for Patients with Sick Sinus Syndrome

<table>
<thead>
<tr>
<th>Indication</th>
<th>Type of pacemaker</th>
</tr>

<tbody>
<tr>
<td>Sick sinus syndrome with normal atrioventricular conduction</td>
<td>Dual chamber pacing or atrial inhibited pacing</td>
</tr>
<tr>
<td>Sick sinus syndrome with known atrioventricular conduction abnormality (including bundle branch block and bifascicular block)</td>
<td>Dual chamber pacing</td>
</tr>
</tbody>
</table>

NOTE: Dual chamber pacing is the preferred pacemaker setting for this indication because of the propensity of patients to develop atrioventricular block; however, atrial inhibited pacing can also be used.
