Clinical Question
Which interventions are effective for treating symptoms of the common cold?

Evidence-Based Answer
There is no single treatment that produces significant improvements in symptoms of the common cold. Intranasal ipratropium (Atrovent) can be given to reduce rhinorrhea. (Strength of Recommendation [SOR]: A, based on a systematic review of randomized controlled trials [RCTs].) Oral zinc can be given therapeutically to shorten cold duration and severity, and can be taken prophylactically to reduce the risk of colds. (SOR: A, based on a systematic review of RCTs.) Vitamin C should not be used therapeutically. (SOR: A, based on a systematic review of RCTs.) Nonsteroidal anti-inflammatory drugs should not be used for acute cold symptoms. (SOR: A, based on a systematic review of RCTs.)

Pelargonium sidoides, Echinacea purpurea, and intranasal saline may be used for symptoms of the common cold. (SOR: C, based on a systematic review of inconsistent RCTs.) Antihistamines and antibiotics should not be used (SOR: A, based on systematic reviews of RCTs), nor should intranasal zinc (SOR: C, based on a case series). Over-the-counter preparations should not be used in children younger than six years because they are more likely to produce harm than benefit. (SOR: C, based on expert consensus.)

Likely Effective
Intranasal administration of ipratropium decreases rhinorrhea symptoms, but has no effect on nasal congestion. Therapeutic use of oral zinc reduces the duration and severity of colds when taken within 24 hours of symptom onset. Prophylactic use of oral zinc reduces the incidence of cold, school and work absences, and antibiotic prescriptions. Adverse effects, such as bad taste and nausea, are common. High-dose vitamin C does not prevent colds, but when used prophylactically it reduces the duration of colds by 8% and reduces cold symptoms, especially in children. Nonsteroidal anti-inflammatory drugs reduce pain associated with the common cold, but do not shorten cold duration or overall respiratory symptom scores.

Possibly Effective
A liquid preparation of the herb P. sidoides may slightly reduce the duration of sputum production and cough in adults and children with acute bronchitis. Therapeutic use of E. purpurea may improve cold symptoms in adults, but the evidence is inconsistent. Intranasal saline may produce limited symptomatic benefit in adults, but children may not be able to tolerate it.

Unknown Effectiveness
There is inadequate evidence to evaluate the effectiveness of garlic, honey, conjugated linoleic acid, hot liquids, humidified air, sea buckthorn berries, ginseng, Chinese herbal medicines, homeopathy, acupuncture, and enhanced physician empathy.

INEFFECTIVE

Antihistamines alone, prophylactic use of Echinacea preparations, and antibiotics are ineffective for treating symptoms of the common cold. When started after symptom onset, vitamin C is also ineffective.

HARMS OUTWEIGH BENEFITS

Over-the-counter cough and cold medications for children younger than six years are ineffective and are associated with overdose and toxicity. Intranasal zinc can cause permanent anosmia.

Recommendations from Others

The American College of Chest Physicians recommends treating common cold symptoms with a first-generation antihistamine/decongestant preparation and naproxen. The U.S. Food and Drug Administration recommends that over-the-counter cough and cold medications should not be used in children younger than two years because of potentially life-threatening adverse effects. The American Academy of Pediatrics makes a similar recommendation, and says that studies show that these medications have little benefit in children younger than six years.
