Diagnosis and Management of ADHD in Children

BARBARA T. FELT, MD, MS, and BERNARD BIERMANN, MD, PhD, University of Michigan, Ann Arbor, Michigan
JENNIFER G. CHRISTNER, MD, State University of New York Upstate Medical University, Syracuse, New York
PARAM KOCHHAR, MD, MBBS, and RICHARD VAN HARRISON, PhD, University of Michigan, Ann Arbor, Michigan

Attention-deficit/hyperactivity disorder (ADHD) is the most common behavioral disorder in children, and the prevalence is increasing. Physicians should evaluate for ADHD in children with behavioral concerns (e.g., inattention, hyperactivity, impulsivity, oppositionality) or poor academic progress using validated assessment tools with observers from several settings (home, school, community) and self-observation, if possible. Physicians who inherit a patient with a previous ADHD diagnosis should review the diagnostic process, and current symptoms and treatment needs. Coexisting conditions (e.g., anxiety, learning, mood, or sleep disorders) should be identified and treated. Behavioral treatments are recommended for preschool-aged children and may be helpful at older ages. Effective behavioral therapies include parent training, classroom management, and peer interventions. Medications are recommended as first-line therapy for older children. Psychostimulants, such as methylphenidate and dextroamphetamine, are most effective for the treatment of core ADHD symptoms and have generally acceptable adverse effect profiles. There are fewer supporting studies for atomoxetine, guanfacine, and clonidine, and they are less effective than the psychostimulants. Height, weight, heart rate, blood pressure, symptoms, mood, and treatment adherence should be recorded at follow-up visits. (Am Fam Physician. 2014;90(7):456-464. Copyright © 2014 American Academy of Family Physicians.)

Attention-deficit/hyperactivity disorder (ADHD) is the most common behavioral disorder in childhood. The prevalence increased by an estimated 3% annually between 1997 and 2006.1 Recent national data show that up to 11% of four- to 17-year-olds have had an ADHD diagnosis,1,2 8.8% currently have the diagnosis, and 6.1% are receiving a medication for ADHD.2

Adolescents with ADHD have higher rates of motor vehicle crashes, substance abuse, and school drop out.3 Medication is effective for treating ADHD symptoms, and studies suggest that earlier identification and treatment may improve longer-term educational, work, and social outcomes.4–7 This article is based on the University of Michigan Health System guideline for ADHD and includes information from other guidelines and reviews.8–11

Etiology

Although the etiology of ADHD is not fully understood, genetic and neurologic factors play important roles. ADHD is two to eight times more common in persons who have a first-degree relative with the condition.12,13 In addition, ADHD is associated with deficits in brain structure, and neuronal functioning and connectivity, which appear to be correlated with ADHD severity.14,15

Clinical Presentation

The diagnosis of ADHD should be considered in patients four years or older with poor attention, distractibility, hyperactivity, impulsiveness, poor academic performance, or behavioral problems at home or at school.8–10 More boys have ADHD overall; however, the inattentive subtype is more common in girls.8–10 Although no evidence supports universal screening for ADHD at well visits, physicians should be attentive to patients’ and guardians’ concerns about academic performance and behavioral problems.9

Evaluation

The evaluation of ADHD in children and adolescents (Figure F8–11) includes a history and physical examination, review of information across home and community settings (Table Fi8–9), and application of the
ADHD in Children

ADHD in Children

ADHD cannot be reliably diagnosed in children younger than four years. Although it is difficult to determine whether symptoms are beyond the expected behavior of four- and five-year-olds, validated behavioral rating scales for this age group can improve diagnostic confidence.

OLDER CHILDREN

Children typically present with ADHD symptoms during the early school years. Patients with primarily...
hyperactive-impulsive or combined types may present with behaviors considered as problematic before those with primarily inattentive features. Patients with the primarily inattentive type may not present until academic requirements become greater (e.g., by the fourth grade). A comorbid learning disorder should be considered if academic progress is poor. Patients should be assessed for sleep problems, such as obstructive sleep apnea, particularly those with snoring and daytime behavioral problems; adenotonsillar hypertrophy; neuromuscular abnormalities; or obesity.24,25

### ADOLESCENTS

New onset of ADHD symptoms is less common beyond 12 years of age, but may occur because of increased academic demands or if subtle symptoms are unrecognized at an earlier age. Learning disabilities, mental health conditions, sleep problems, and substance abuse should be considered because they may mimic ADHD or be a comorbidity. Two teachers who know the patient well, and possibly other supervisory adults (e.g., coaches, group leaders), should provide information about the patient’s symptoms. Behavioral rating scales are also available for self-report at this age.8,9,21

### Treatment

The goal of ADHD treatment is to improve symptoms, optimize functional performance, and remove behavioral obstacles. The primary care physician should provide families with ADHD-specific resources (Table 5) and general parenting advice. Children with ADHD may qualify for accommodations at school under section 504 of the Rehabilitation Act or under the Individuals with Disabilities Education Act. Parents can request an evaluation to determine eligibility for these accommodations or for an individualized education plan (IEP) through their child’s school district.

Treatment of children younger than six years should begin with behavioral therapy.8,9,21 Medications may be considered if ADHD symptoms are moderate to severe and not responsive to behavioral therapy.8,9 Therapy should start with medications in children six years and older. Behavioral treatments are also recommended for older children; however, they are particularly helpful if medication response is poor or associated with adverse effects.8,10

#### BEHAVIORAL THERAPIES

The Multimodal Treatment Study of Children with ADHD assessed treatment effects in 579 children seven to nine years of age. Patients received intensive behavioral therapy, medication, combined behavioral therapy and medication, or standard treatment by community physicians over 14 months. Similar benefits were observed for behavior, social skills, relationships and academics in children who received medication alone compared with those who received medication and behavioral therapy.4 Longer-term analyses suggest that behavioral treatment provides additional benefits beyond medication alone, particularly regarding treatment satisfaction for parents and teachers and in children with lower socioeconomic status.9,27-29

Effective behavioral therapies include parent training, classroom management, peer interventions, and combinations of these interventions.30,31 Parent training, in group or individual formats, provides education to improve their understanding about ADHD, behavioral problems, and child development. This training also helps them employ positive parenting strategies (e.g., praise and rewards for targeted behaviors) and reduce disruptive child behaviors (e.g., planned ignoring of behavior and use of consequences). Treatment often involves seven to 12 weekly sessions and has demonstrated improved child behavior and parent satisfaction.30,31

---

**Table 1. Evaluation of ADHD in Children and Adolescents**

| Interview: report of ADHD symptoms across contexts (see Table 2 for diagnostic criteria) |
| Parent/caretaker report of symptoms for ADHD and other disorders (e.g., learning, mental health, sleep problems) in the home setting |
| School/community report of symptoms outside of the home |
| Patient report of symptoms and degree of impact on current functioning; particularly helpful for older children and adolescents |
| School or work performance: progress reports, absenteeism, grade retention, special education services, referrals for behavioral or legal problems |
| Consider coexisting or mimicking conditions (Table 3) |
| Review history |
| Medical: birth history and early developmental progression, medical and mental health evaluation and treatment, past and current medications |
| Social: family social and financial support, family stressors |
| Family: history of ADHD, other mental health or legal concerns |
| Physical examination: includes complete cardiac and neurologic examinations, vision and hearing screening |
| Behavioral ratings: validated ADHD screening test or assessment from parent, teacher, or self-report (see Table 4 for screening tools) |

ADHD = attention-deficit/hyperactivity disorder.

Information from references 8 and 9.
## Table 2. Diagnostic Criteria for Attention-Deficit/Hyperactivity Disorder

A. A persistent pattern of inattention and/or hyperactivity-impulsivity that interferes with functioning or development, as characterized by (1) and/or (2):

1. **Inattention:** Six (or more) of the following symptoms have persisted for at least six months to a degree that is inconsistent with developmental level and that negatively impacts directly on social and academic/occupational activities:
   
   **Note:** The symptoms are not solely a manifestation of oppositional behavior, defiance, hostility, or failure to understand tasks or instructions. For older adolescents and adults (age 17 and older), at least five symptoms are required.

   a. Often fails to give close attention to details or makes careless mistakes in schoolwork, at work, or during other activities (e.g., overlooks or misses details, work is inaccurate).
   
b. Often has difficulty sustaining attention in tasks or play activities (e.g., has difficulty remaining focused during lectures, conversations, or lengthy reading).
   
c. Often does not seem to listen when spoken to directly (e.g., mind seems elsewhere, even in the absence of any obvious distraction).
   
d. Often does not follow through on instructions and fails to finish schoolwork, chores, or duties in the workplace (e.g., starts tasks but quickly loses focus and is easily sidetracked).
   
e. Often has difficulty organizing tasks and activities (e.g., difficulty managing sequential tasks; difficulty keeping materials and belongings in order; messy, disorganized work; has poor time management; fails to meet deadlines).
   
f. Often avoids, dislikes, or is reluctant to engage in tasks that require sustained mental effort (e.g., schoolwork or homework; for older adolescents and adults, preparing reports, completing forms, reviewing lengthy papers).
   
g. Often loses things necessary for tasks or activities (e.g., school materials, pencils, books, tools, wallets, keys, paperwork, eyeglasses, mobile telephones).
   
h. Is often easily distracted by extraneous stimuli (for older adolescents and adults, may include unrelated thoughts).
   
i. Is often forgetful in daily activities (e.g., doing chores, running errands; for older adolescents and adults, returning calls, paying bills, keeping appointments).

2. **Hyperactivity and impulsivity:** Six (or more) of the following symptoms have persisted for at least six months to a degree that is inconsistent with developmental level and that negatively impacts directly on social and academic/occupational activities:
   
   **Note:** The symptoms are not solely a manifestation of oppositional behavior, defiance, hostility, or a failure to understand tasks or instructions. For older adolescents and adults (age 17 or older), at least five symptoms are required.

   a. Often fidgets with or taps hands or feet or squirms in seat.
   
b. Often leaves seat in situations when remaining seated is expected (e.g., leaves his or her place in the classroom, in the office or other workplace, or in other situations that require remaining in place).
   
c. Often runs about or climbs in situations where it is inappropriate. **(Note:** In adolescents or adults, may be limited to feeling restless.)
   
d. Often unable to play or engage in leisure activities quietly.
   
e. Is often “on the go,” acting as if “driven by a motor” (e.g., is unable to be or uncomfortable being still for extended time, as in restaurants, meetings; may be experienced by others as being restless or difficult to keep up with).
   
f. Often talks excessively.
   
g. Often blurts out an answer before a question has been completed (e.g., completes people’s sentences; cannot wait for turn in conversation).
   
h. Often has difficulty waiting his or her turn (e.g., while waiting in line).
   
i. Often interrupts or intrudes on others (e.g., butts into conversations, games, or activities; may start using other people’s things without asking or receiving permission; for adolescents and adults, may intrude into or take over what others are doing).

B. Several inattentive or hyperactive-impulsive symptoms were present prior to age 12 years.

C. Several inattentive or hyperactive-impulsive symptoms are present in two or more settings (e.g., at home, school, or work; with friends or relatives; in other activities).

D. There is clear evidence that the symptoms interfere with, or reduce the quality of, social, academic, or occupational functioning.

E. The symptoms do not occur exclusively during the course of schizophrenia or another psychotic disorder and are not better explained by another mental disorder (e.g., mood disorder, anxiety disorder, dissociative disorder, personality disorder, substance intoxication or withdrawal).

Table: Pharmacologic Treatment

**Pharmacologic Treatment**

Medications reduce core ADHD symptoms for most children.\textsuperscript{6-11} Table 6 summarizes common ADHD medications.\textsuperscript{8,9,32} Psychostimulants (e.g., methylphenidate [Ritalin], dextroamphetamine, and mixed amphetamine salts such as dextroamphetamine/amphetamine [Adderall]) are the most effective and safe option, and are the first

management focuses on strategies to improve classroom routines and structure, a token economy to shape positive behaviors, and a daily behavioral report card to monitor progress and provide feedback to the child, parent, and team.\textsuperscript{30,31} Peer interventions include social skills training and time-intensive, adult-mediated interactions to improve social behaviors.\textsuperscript{30,31}
choice for ADHD treatment in national guidelines and reviews.\textsuperscript{8,9} Atomoxetine (Strattera) and alpha-2 receptor agonists (e.g., guanfacine [Tenex], clonidine [Catapres]) are also effective but have fewer supporting studies and are less effective than psychostimulants.\textsuperscript{8} Reasons for starting with a second-line drug include strong family preference for a nonstimulant medication, concern about drug divergence (although some long-acting stimulants reduce this risk), or comorbid conditions that might also be managed by a single medication (e.g., an anxiety or tic disorder).\textsuperscript{3,8,9}

Other medications used for ADHD include antidepressants (e.g., bupropion [Wellbutrin], trazodone), atypical antipsychotics (e.g., risperidone [Risperidal], aripiprazole [Abilify]), and mood stabilizers (e.g., carbamazepine [Tegretol]). These are not approved by the U.S. Food and Drug Administration for treating ADHD and are used off-label when psychostimulants, atomoxetine, or alpha-2 receptor agonists are ineffective, or for treatment of comorbid conditions.\textsuperscript{8,9}

\textbf{Psychostimulants}. These medications affect central nervous system dopaminergic pathways. In addition to symptom reduction, academic performance may also improve; children with ADHD who are taking a stimulant are less likely to be held back a grade.\textsuperscript{6} Stimulant medication does not increase the incidence of substance abuse and may improve driving performance in

\hline
Anxiety disorder: generalized (excessive, pervasive worries); obsessive-compulsive (recurrent and persistent thoughts, impulses, and/or behaviors); separation (developmentally inappropriate worries at separation [e.g., from a parent])

Autism spectrum disorders (functional impairment as a result of persistent deficits in social communication and interaction, and restricted and repetitive behaviors, interests, or activities)

Fetal alcohol syndrome (history of maternal alcohol use during pregnancy, learning and behavioral problems, physical findings such as a thin upper lip and reduced or absent philtrum)

Genetic: fragile X syndrome (large forehead, ears, jaw; developmental problems/lower IQ; hyperactive-impulsive behavior, poor social skills; neurofibromatosis (cafe au lait spots; tumors of the skin, iris, nerves); 22q11 deletion syndrome (developmental delay, heart abnormalities, cleft palate, distinctive facial features)

Hearing loss

Intellectual disability

Learning disorder (problems with reading, mathematics, written expression)

Mood disorder: dysthymia (chronic mild depression), major depression (pervasive depressed mood), bipolar (periods of manic and/or depressed mood)

Oppositional defiant disorder (negative, hostile, defiant behavior)

Seizure disorder

Sleep disorder (obstructive sleep apnea, restless legs syndrome, periodic limb movement disorder)

Speech and language disorder (receptive, expressive, mixed)

Vision disorder

younger drivers who have ADHD. About 70% of patients respond to the first stimulant medication, and 90% to 95% respond to a second stimulant. Of the medication studies involving preschool children, methylphenidate is most supported.

Adverse effects of stimulant medication are generally dose dependent and include reduced appetite, abdominal discomfort, headache, irritability, anxiousness, sleep problems, and a small reduction in height velocity that may attenuate with time and/or reverse after

Information from references 8, 9, and 32.

Adverse effects include somnolence, gastrointestinal upset/nausea (particularly if the dose is advanced too quickly), and reduced appetite. Full therapeutic effect is reached in about four to six weeks.8,9

**Alpha-2** receptor agonists. These antihypertensive agents are also beneficial as alternatives or adjuncts to stimulant treatment for ADHD. Potential advantages of guanfacine over clonidine include a longer half-life and discontinuation of treatment.8,9,37 Preschoolers may also have mood lability.38 Although depression and suicidal ideation are rare, family members should be informed about the risk. Small increases in heart rate and blood pressure have also been observed; significant elevations are rare. Evidence that stimulants increase the risk of cardiac problems is conflicting.39 National guidelines recommend that physicians consider electrocardiography and/or cardiology referral before initiating psychostimulants in patients with a history of heart disease, palpitations, syncope, or seizures, or with a family history of sudden cardiac death, Wolff-Parkinson-White syndrome, hypertrophic cardiomyopathy, or long QT syndrome.8,9,37,39

Tic and Tourette syndrome symptoms affect about 2% to 12% of the general population, but about 20% of patients with ADHD.40 The presence of tics is not a contraindication for stimulant use; however, the current consensus is that although stimulant use does not clearly worsen tics, it may do so in individual cases. Treatment with atomoxetine or the addition of an alpha-2 receptor agonist may lessen comorbid tics.8,9,37,40

Psychostimulant dosing should start low and increase once to twice weekly based on feedback from parents, the patient, and teachers. No evidence shows that one psychostimulant agent is superior.8,9,41 A younger child who cannot swallow pills may benefit from liquid or spansule preparations (which can be sprinkled on food). An older child or teenager may benefit from long-acting preparations and/or the addition of a short-acting compound after school to provide sufficient coverage for homework or other activities. Long-acting preparations have the advantage of less frequent dosing but can be more costly than short-acting options.

**Atomoxetine.** Atomoxetine is a nonstimulant medication that affects noradrenergic systems. Atomoxetine may also be effective for comorbid mood or anxiety disorders and has no abuse risk. These factors may be beneficial in the treatment of adolescents with ADHD.3,9,42 Adverse effects include somnolence, gastrointestinal upset/nausea (particularly if the dose is advanced too quickly), and reduced appetite. Full therapeutic effect is reached in about four to six weeks.8,9
fewer sedative and hypotensive effects. Both are useful in combination with stimulants for patients who have ADHD and comorbid sleep problems, tics, or Tourette syndrome.8,9

MONITORING

Physician follow-up is recommended one month after initiating treatment. Height, weight, heart rate, blood pressure, symptoms, mood, and treatment adherence should be monitored at follow-up visits. Monthly visits may be required until medication dosing and timing are optimized. When an acceptable regimen is determined, follow-up is recommended at least every three months during the first year, and two or three times per year thereafter to assess control of symptoms, treatment adherence, and the presence of comorbid conditions.8,9 Medication holidays are unnecessary unless adverse effects (e.g., decreased growth velocity) are a concern.8,9

Data Sources: In addition to the literature search for the University of Michigan Health System guideline, we searched Essential Evidence Plus, the Cochrane Library, and the National Guideline Clearinghouse using the key terms attention deficit disorder and attention deficit disorder with hyperactivity, and combined with the additional search terms general treatment, drug treatment, harm, risk factors, and guidelines. Search dates: March 18, 2013, and June 4, 2014.

The authors thank Ms. Ellen Patrick-Dunlavey for her assistance in the preparation of the manuscript.
