Teenager with a Bleeding, Red Papule

ELIZABETH SEIVERLING, MD; DANIEL McLAUGHLIN, BA; and OBSITU KELIFA, MSN, MPH
Pennsylvania State University College of Medicine, Hershey, Pennsylvania

The editors of AFP welcome submissions for Photo Quiz. Guidelines for preparing and submitting a Photo Quiz manuscript can be found in the Authors’ Guide at http://www.aafp.org/afp/photoquizinfo. To be considered for publication, submissions must meet these guidelines. E-mail submissions to afpphoto@aafp.org.

This series is coordinated by John E. Delzell, Jr., MD, MSPH, Assistant Medical Editor.

A collection of Photo Quiz published in AFP is available at http://www.aafp.org/afp/photoquiz.

Previously published Photo Quizzes are now featured in a mobile app. Get more information at http://www.aafp.org/afp/apps.

A 14-year-old boy presented with a tender red papule on his finger. He first noticed it two months earlier. It bled several times, especially when rubbed by his baseball mitt. He had no medical problems or allergies, and he was not taking any medications. He had no other similar skin lesions, and the review of systems was negative for bleeding problems, easy bruising, and frequent infections.

Physical examination revealed a solitary bright-red papule on the distal lateral portion of his left fifth finger (Figure 1). On dermoscopy, the lesion was homogeneously red and surrounded by a white collarette of scale (Figure 2). There was no evidence of a pigment network, pigment globules, or dotted vessels.

Question
Based on the patient’s history, physical examination, and dermoscopy findings, which one of the following is the most likely diagnosis?

A. Amelanotic melanoma.
B. Hemangioma.
C. Pyogenic granuloma.
D. Spitz nevus.
E. Wart.

See the following page for discussion.
### Summary Table

<table>
<thead>
<tr>
<th>Condition</th>
<th>Clinical characteristics</th>
<th>Dermoscopy findings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amelanotic melanoma</td>
<td>Pink or skin-colored plaques, typically on sun-exposed sites</td>
<td>Milky red globules, polymorphous vessels, or dotted vessels</td>
</tr>
<tr>
<td>Hemangioma of infancy</td>
<td>Benign vascular tumor that appears shortly after birth and involutes spontaneously</td>
<td>Red lacunae (or lagoons) of dilated blood vessels separated by white septa</td>
</tr>
<tr>
<td>Pyogenic granuloma</td>
<td>Small vascular papule that appears abruptly, typically after trauma or starting a new medication</td>
<td>Homogeneous red area with a white collarette</td>
</tr>
<tr>
<td>Spitz nevus</td>
<td>Brown, pink, or red dome-shaped papule composed of melanocytes</td>
<td>Dotted vessels or a starburst pattern of pigment at the periphery</td>
</tr>
<tr>
<td>Wart</td>
<td>Viral infection causing firm, hyperkeratotic papules with scale, often on the hands or feet</td>
<td>Homogeneous black to red dots (thrombosed capillaries) and globules</td>
</tr>

</table>

### Discussion

The answer is C: pyogenic granuloma. Pyogenic granulomas are more accurately described as lobular capillary hemangiomas because the lesions are not purulent or granulomatous. They are benign vascular tumors that typically evolve over weeks to months, rarely growing larger than 1 cm. They can occur at any age but are most common in children and young adults. Most are solitary, and they are often attributed to trauma. They are also associated with several medications, including isotretinoin, capecitabine (Xeloda), and indinavir (Crixivan). On dermoscopy, 92% of pyogenic granulomas have a homogeneous reddish area and 85% have a white collarette; the combination of these two findings was found to be 100% specific for pyogenic granulomas.

Treatment of a pyogenic granuloma is typically surgical, although spontaneous resolution has been reported. Shave removal is often sufficient because they are small and superficial. For smaller lesions, silver nitrate alone may be applied instead of shave removal. For larger lesions, silver nitrate may be applied after excision or curettage may be performed to remove remaining tissue. Some pyogenic granulomas have features similar to malignant lesions. In these lesions, a biopsy with histopathologic analysis should be performed. Recurrence is common, especially if the removal is too superficial and a portion of the lesion persists after the excision.

Amelanotic melanomas present as pink or skin-colored plaques, typically on sun-exposed sites. They lack the classic dark or multicolored presentation of typical melanomas. On dermoscopy, amelanotic melanomas may have milky red globules, polymorphous vessels, or dotted vessels similar to those of Spitz nevi. Diagnosis requires histologic analysis.

Hemangiomas are benign vascular proliferations. Most hemangiomas appear within the first few months of life and involute spontaneously. On dermoscopy, hemangiomas have red lacunae (or lagoons) of dilated blood vessels separated by white septa. Spitz nevi are brown, pink, or red dome-shaped papules composed of melanocytes. Spitz nevi are more common in children, whereas malignant spitzoid melanoma is more common in adults. On dermoscopy, up to 78% of Spitz nevi have dotted vessels. A starburst pattern, where melanocytes radiate out symmetrically from the edge of the lesion, is also seen with Spitz nevi. Because of the clinical similarities between Spitz nevi and spitzoid melanoma, lesions with dotted vessels or a starburst pattern on dermoscopy are typically biopsied.

Warts (verrucae) are caused by a common viral infection and often affect the hands and feet. Warts may be solitary or multiple. They are usually firm, hyperkeratotic papules with scale, and they occasionally bleed. On dermoscopy, homogeneous black to red dots (thrombosed capillaries) and globules are seen in 79% of warts.
