

# Diagnosis and Management of Adnexal Masses

WENDY S. BIGGS, MD, and SARAH TULLY MARKS, MD, *University of Kansas, Kansas City, Kansas*

Adnexal masses can have gynecologic or nongynecologic etiologies, ranging from normal luteal cysts to ovarian cancer to bowel abscesses. Women who report abdominal or pelvic pain, increased abdominal size or bloating, difficulty eating, or rapid satiety that occurs more than 12 times per month in less than a year should be evaluated for ovarian cancer. Pelvic examination has low sensitivity for detecting an adnexal mass; negative pelvic examination findings in a symptomatic woman should not deter further workup. Ectopic pregnancy must be ruled out in women of reproductive age. A cancer antigen 125 (CA 125) test may assist in the evaluation of an adnexal mass in appropriate patients. CA 125 levels are elevated in conditions other than ovarian cancer. Because substantial overlap in CA 125 levels between pre- and postmenopausal women may occur, this level alone is not recommended for differentiating between a benign and a malignant adnexal mass. Transvaginal ultrasonography is the first choice for imaging of an adnexal mass. Large mass size, complexity, projections, septation, irregularity, or bilaterality may indicate cancer. If disease is suspected outside of the ovary, computed tomography may be indicated; magnetic resonance imaging may better show malignant characteristics in the ovary. Serial ultrasonography and periodic measurement of CA 125 levels may help in differentiating between benign or potentially malignant adnexal masses. If an adnexal mass larger than 6 cm is found on ultrasonography, or if findings persist longer than 12 weeks, referral to a gynecologist or gynecologic oncologist is indicated. ► **Patient information:**

A handout on this topic, written by the authors of this article, is available at <http://www.aafp.org/afp/2016/0415/p676-s1.html>.

The etiology of adnexal masses ranges from physiologically normal luteal cysts to ovarian cancer. The clinician needs to interpret symptoms and findings from multiple organ systems and use appropriate imaging to differentiate expeditiously between a benign and a malignant cause of an adnexal mass. Ovarian malignancy is diagnosed approximately 22,000 times per year in the United States, making it the second most common gynecologic cancer; in 2010, nearly 14,000 women died of ovarian cancer.<sup>1,2</sup> Screening for ovarian cancer has not been demonstrated to be effective in the general population. With no effective screening measures available, 70% of ovarian malignancies are diagnosed at a late stage.<sup>3</sup> However, when ovarian cancer is detected at a stage confined to the ovary, survival rates can approach 90% at five years.<sup>3</sup>

The differential diagnosis for adnexal masses is broad. A previous *American Family Physician* article gives a complete list.<sup>4</sup> The gynecologic causes of adnexal masses include benign sources, such as luteal cysts, polycystic ovaries, ectopic pregnancy, and

tubo-ovarian abscess. Malignant causes include endothelial carcinoma, sarcoma, and borderline tumors. Because adnexal masses can have gastrointestinal, urinary, or metastatic sources, ovarian origin should not be assumed. Abscesses, cysts, and cancers of the gastrointestinal tract or other abdominal or pelvic organs can appear as adnexal masses on imaging or examination, and breast and colon cancer can metastasize in ovaries.

## History

Clinical history is vital in the diagnosis of an adnexal mass (*Table 1*).<sup>4</sup> Risk of ovarian cancer increases with age. The patient's reproductive status and contraception method must be determined; ectopic pregnancy can be a life-threatening adnexal mass. Women with a family history of breast and gynecologic cancers, those with known or suggested presence of *BRCA* or other hereditary cancer syndromes, and women of Ashkenazi Jewish descent are at increased risk of ovarian cancer. Other risk factors for ovarian cancer include nulliparity, obesity, delayed child-bearing, use of fertility-enhancing medications, and unopposed estrogen exposure.<sup>4,5</sup>

## SORT: KEY RECOMMENDATIONS FOR PRACTICE

<i>Clinical recommendation</i>	<i>Evidence rating</i>	<i>References</i>
Women who report abdominal or pelvic pain, increased abdominal size or bloating, or difficulty eating or feeling full quickly more than 12 times per month for less than 12 months' duration should be evaluated for ovarian cancer.	C	3
The U.S. Preventive Services Task Force recommends against routine screening for ovarian cancer, including use of transvaginal ultrasonography, cancer antigen 125 testing, and screening pelvic examinations.	A	10
An adnexal mass occurring during pregnancy can be managed expectantly because the risk of malignancy is low.	C	18, 19, 21, 22
Transvaginal ultrasonography should be the first imaging test used to identify and characterize an adnexal mass.	C	6
Cancer antigen 125 testing alone should not be used to differentiate between a benign and a malignant adnexal mass.	C	6, 16

*A = consistent, good-quality patient-oriented evidence; B = inconsistent or limited-quality patient-oriented evidence; C = consensus, disease-oriented evidence, usual practice, expert opinion, or case series. For information about the SORT evidence rating system, go to <http://www.aafp.org/afpsort>.*

**Table 1. Selected Clinical Entities in the Differential Diagnosis of Adnexal Tenderness or Mass**

<i>Condition</i>	<i>Suggestive symptoms</i>	<i>Possible physical examination finding</i>
Ectopic pregnancy	Lower abdominal (usually unilateral and severe) or pelvic pain	Adnexal mass or tenderness, hypotension, tachycardia
Endometrioma	Abnormal uterine bleeding, dyspareunia, worsening pain with menses	Adnexal mass or tenderness, tenderness over uterosacral ligaments
Functional ovarian cyst (corpus luteum)	Unilateral pelvic pain, pain during middle of menstrual cycle (mittelschmerz), pain with intercourse	Adnexal mass or tenderness
Leiomyoma	Dysmenorrhea, menorrhagia	Abdominal mass, uterine enlargement
Ovarian cancer	Pelvic or abdominal pain, abdominal fullness and pressure, bloating, difficulty eating, early satiety, increased abdominal size, indigestion, dyspareunia, urinary urgency or frequency, incontinence	Abdominal or adnexal mass, ascites, lymphadenopathy, nodularity of uterosacral ligaments, pleural effusion
Ovarian torsion	Sudden onset of unilateral and severe lower abdominal or pelvic pain, associated with nausea or vomiting	Abdominal or adnexal tenderness
Pelvic inflammatory disease or tubo-ovarian abscess	Fever, lower abdominal or pelvic pain, nausea, vaginal discharge, vomiting	Abdominal or adnexal tenderness, cervical motion tenderness, fever, vaginal discharge
Polycystic ovary syndrome	Oligomenorrhea, amenorrhea, or menorrhagia associated with obesity and hirsutism	Unilateral or bilateral adnexal fullness or enlarged ovary or ovaries

*Adapted with permission from Givens V, Mitchell G, Harraway-Smith C, Reddy A, Maness DL. Diagnosis and management of adnexal masses. Am Fam Physician. 2009;80(8):817.*

Adhesions from previous abdominal or pelvic surgery can cause symptomatology similar to an adnexal mass.

Common symptoms associated with adnexal masses include irregular vaginal bleeding, bloating, increased abdominal girth, dyspareunia, urinary symptoms, pelvic pain, and abdominal pain.<sup>1,6,7</sup> Ovarian cancer can occur in a premenarchal patient, and symptoms suggestive of an adnexal mass should not be ignored in that population. Pain, increased abdominal size, bloating, and urinary symptoms may be more indicative of malignant rather

than benign causes<sup>7</sup> (Table 2<sup>8</sup>). More severe, frequent symptoms of shorter duration may also indicate cancer.

Studies have investigated the creation of a symptom index to evaluate the constellation of possible indicators and their presence over time, but no single index is widely accepted.<sup>1,3</sup> One symptom index study recommends that women who report abdominal or pelvic pain, increased abdominal size or bloating, or difficulty eating or feeling full quickly more than 12 times per month for less than 12 months' duration be evaluated for ovarian cancer.<sup>3</sup>

**Table 2. Sensitivity and Specificity of Symptoms to Identify Patients with Ovarian Cancer**

Symptom	Sensitivity (%)	Specificity (%)	LR+	LR-
Four or more symptoms	27	96	6.75	0.76
Three or more symptoms	43	92	5.38	0.62
Increased abdominal size	64	81	3.37	0.44
Bloating	70	62	1.84	0.48
Urinary tract symptoms	55	68	1.72	0.66
Abdominal pain	50	70	1.67	0.71
Pelvic pain	41	74	1.58	0.80
Constipation	50	64	1.39	0.78
Diarrhea	25	68	0.78	1.10
Menstrual irregularity	18	75	0.72	1.09
Nausea	14	78	0.64	1.10
Postmenopausal bleeding	2	96	0.50	1.02

NOTE: See <http://www.aafp.org/journals/afp/authors/ebm-toolkit/glossary.html> for a definition of likelihood ratios.

LR+ = positive likelihood ratio; LR- = negative likelihood ratio.

Information from reference 8.

and abdomen. A digital rectal examination should also be considered.

### Laboratory Testing

Laboratory testing should be directed by associated symptoms. In all peri- and premenopausal women, pregnancy must be ruled out with a urine test. Serial quantitative beta human chorionic gonadotropin ( $\beta$ -hCG) tests are helpful in evaluating suspected ectopic pregnancy. In a normal pregnancy, the  $\beta$ -hCG level should increase by more than 50% in two days.<sup>13</sup> An intrauterine pregnancy is indicated when the  $\beta$ -hCG level is greater than the discriminatory zone of 1,500 to 2,000 mIU per mL (1,500 to 2,000 IU per L).<sup>14</sup> Heterotopic pregnancy, when both an intra- and extrauterine pregnancy exist, occurs in an estimated one per 30,000 pregnancies from spontaneous conceptions,

whereas it can occur in up to 1% of pregnancies after assistive reproductive methods.<sup>15</sup>

A complete blood count with differential may help to evaluate an adnexal mass. An elevated white blood cell count may suggest pelvic inflammatory disease, a tubo-ovarian abscess, or a pelvic abscess from colonic or appendiceal sources.

Although cancer antigen 125 (CA 125) testing should not be used as a screening tool, a CA 125 level may assist in the evaluation of an adnexal mass in select patients. CA 125 levels may be elevated in a number of conditions other than ovarian cancer (Table 3).<sup>16</sup> There is substantial overlap in CA 125 levels between pre- and postmenopausal women.<sup>16</sup> Stage 1 invasive ovarian cancers

### Physical Examination

In 2014, the American College of Physicians recommended against screening pelvic examinations in asymptomatic, nonpregnant adult women.<sup>9</sup> For women without known genetic mutations that increase the risk of ovarian cancer, such as *BRCA* mutations, the U.S. Preventive Services Task Force and the American Academy of Family Physicians recommend against screening for ovarian cancer, including pelvic examination.<sup>10</sup> No ovarian cancers were detected by bimanual pelvic examination in the Prostate, Lung, Colorectal and Ovarian cancer screening trial; thus, the trial discontinued annual bimanual pelvic examination.<sup>11</sup>

In a review of five studies, the pooled sensitivity of pelvic examination for detecting an adnexal mass was 45% with a pooled specificity of 90%.<sup>12</sup> The American College of Physicians' systematic review did not find any studies on the diagnostic accuracy of the pelvic examination for asymptomatic pelvic inflammatory disease, gynecologic cancer other than ovarian or cervical cancer, or benign conditions.<sup>9</sup> Additional evaluation should be directed by the patient's symptoms. For physical symptoms suggestive of an adnexal mass, a pelvic examination, including a speculum examination, should be done. Careful assessment of superficial lymph nodes throughout the body is prudent. Dyspnea or abdominal symptoms should trigger auscultation and examination of the chest

**Table 3. Causes of Elevated Cancer Antigen 125 Levels Not Associated with Ovarian Cancer**

Benign gynecologic causes	Benign nongynecologic causes	Malignancies
Endometriosis, especially endometriomas	Caffeine use	Breast cancer
Large uterine fibroids	Liver cirrhosis	Endometrial cancer
Menstruation	with or without ascites	Lung cancer
Ovarian fibroma	Lung disease	Pancreatic cancer
Pelvic inflammatory disease	Obesity	Peritoneal implants of nonovarian cancers
Previous hysterectomy	Tuberculosis	

Information from reference 16.

may have lower levels of CA 125.<sup>9</sup> A strict laboratory cutoff value of CA 125 alone, therefore, cannot predict malignancy.<sup>6,16</sup>

## Management

### PREMENARCHAL PATIENTS

A retrospective study found that approximately 25% of adnexal masses in patients younger than 18 years were malignant.<sup>17</sup> An adnexal mass in a premenarchal patient, or the presence of symptoms associated with a mass, should prompt referral to a gynecologist with expertise in evaluating these patients.

### PREGNANCY

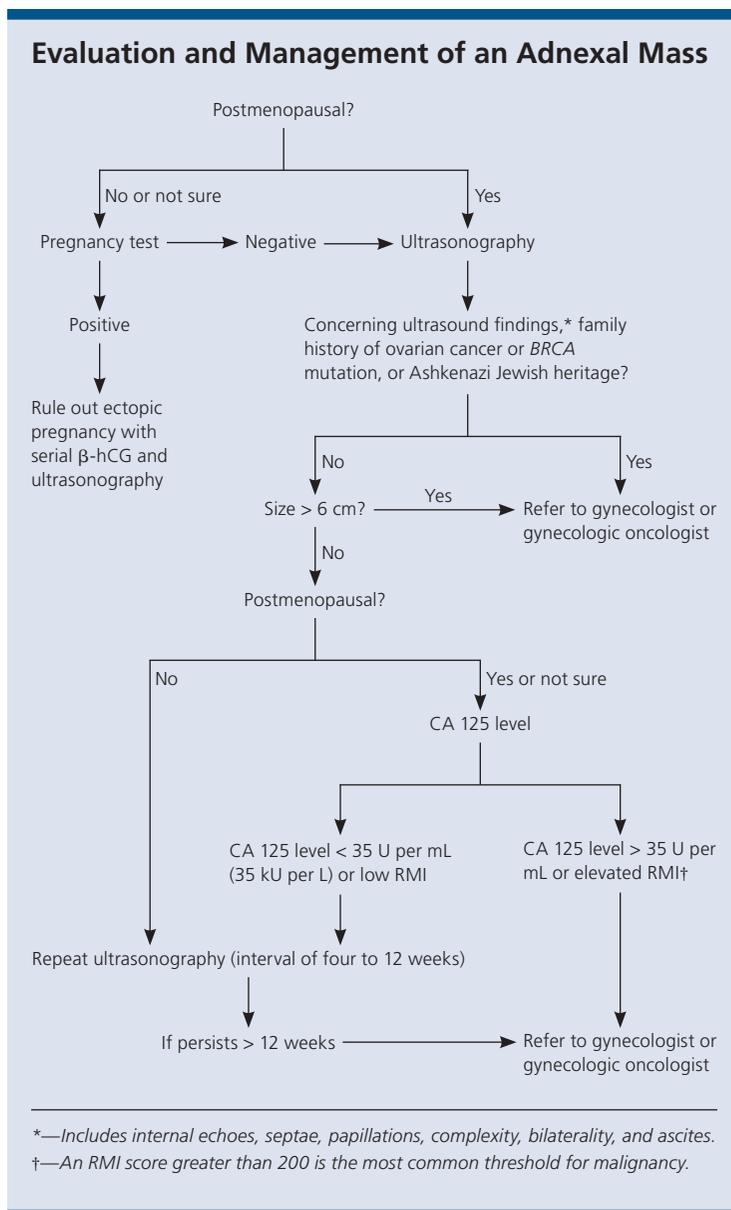

Ectopic pregnancy is the first concern when an adnexal mass is discovered in a pregnant patient (Figure 1).<sup>4</sup> If found, ectopic pregnancy should be managed with appropriate pharmacologic or surgical treatment.<sup>18</sup>

Antepartum ultrasonography commonly detects ovarian cysts in women with an intrauterine pregnancy, with the incidence ranging from 2.3% to 5%,<sup>19</sup> and 76% of simple cysts measuring less than 5 cm.<sup>20</sup> Less than 1% of ovarian masses detected during pregnancy are malignant.<sup>21</sup> Large mass size, complexity, projections, septation, irregularity, or bilaterality may indicate cancer. When ultrasonography is inconclusive, magnetic resonance imaging, following proper radiology protocol, should be used for further characterization of the mass.<sup>22</sup> Most masses detected during pregnancy spontaneously resolve. Observation of persistent ovarian masses during pregnancy has no negative neonatal outcomes<sup>23</sup>; thus, intrapartum surgery is recommended only for rapidly growing or highly suspicious masses.<sup>19</sup> Observation does present a risk of ovarian torsion, especially in pregnancies achieved by assistive reproductive methods.<sup>19,23</sup> The CA 125 level is normally elevated in pregnancy; however, a markedly elevated level may indicate ovarian malignancy and should prompt referral to a gynecologist or gynecologic oncologist.<sup>24</sup>

### NONPREGNANT WOMEN

Clinicians should maintain a high index of suspicion for ovarian cancer in women with

abdominal or pelvic symptoms, especially if the symptoms are new or progressive. Because the sensitivity of pelvic examination is low, further workup in symptomatic women should occur even with negative pelvic examination results.

**Figure 1.** Algorithm for the evaluation and management of an adnexal mass. Key decision points are menopausal status, presence of concerning ultrasound findings, and mass size. ( $\beta$ -hCG = beta human chorionic gonadotropin; CA 125 = cancer antigen 125; RMI = Risk of Malignancy Index.)

Adapted with permission from Givens V, Mitchell G, Harraway-Smith C, Reddy A, Maness DL. Diagnosis and management of adnexal masses. *Am Fam Physician.* 2009;80(8):819.

## Adnexal Masses

Transvaginal ultrasonography is the first choice for imaging to differentiate between a benign and a malignant adnexal mass, with a sensitivity of 93.5% and a specificity of 91.5%.<sup>25</sup> The addition of Doppler to ultrasonography can also aid in differentiation. If disease is suspected outside of the ovary, computed tomography may be indicated, whereas magnetic resonance imaging may show malignant characteristics in the ovary more clearly.<sup>25</sup>

CA 125 testing is not recommended as the sole factor for differentiating between a benign and a malignant adnexal mass.<sup>6,26</sup> CA 125 levels are normally higher in premenopausal women. In most benign conditions, CA 125 levels are less than 20 U per mL (20 kU per L); however, levels up to 45 U per mL (45 kU per L) may be present in women with endometriomas and abscesses.<sup>16</sup> Endometriomas are more prevalent in premenopausal vs. postmenopausal women (32% vs. 2.2%), whereas invasive ovarian malignancies occur three times more often in postmenopausal women (10.5% vs. 39.4%, respectively).<sup>16</sup> In postmenopausal women, a CA 125 level greater than 35 U per mL (35 kU per L) warrants diagnostic ultrasonography, based on a meta-analysis of 49 cohort studies and two case-control studies that found an overall sensitivity of 78.7% and a specificity of 77.9% at a threshold of 35 U per mL.<sup>6</sup> At a CA 125 level of 100 U per mL (100 kU per L), a premenopausal woman has only a 21.1% likelihood of having a malignant ovarian tumor, whereas a postmenopausal woman with the same CA 125 level has a 74.3% likelihood of a malignant ovarian tumor.<sup>16</sup>

Ultrasonography has the possible advantage of earlier detection and, therefore, improved survival and avoidance of unnecessary surgery. Risk of ovarian malignancy increases with ovarian mass size greater than 6 cm, bilaterality, septation, and presence of ascites.<sup>2,27,28</sup> Ultrasound characteristics can be assessed with the CA 125 level and clinical decision-making tools. Several studies have attempted to develop a formula to predict the probability of an adnexal mass.

The Risk of Malignancy Index (RMI) uses menopausal status, ultrasound characteristics, and the CA 125 level in a formula to predict the probability of malignancy (Table 4).<sup>6</sup> Although there is a commonly accepted RMI threshold of greater than 200, studies suggest that different races and ethnicities may have different cutoff values to predict malignancy risk.<sup>29</sup> For example, studies of Asian Pacific populations demonstrate that a cutoff value of 250 showed higher predictability of malignant lesions than the cutoff of 200 used in other populations.<sup>29</sup>

Adnexal findings, such as ovarian cysts, are often discovered incidentally on pelvic computed tomography

or magnetic resonance imaging. Transvaginal ultrasonography should be performed to further characterize the adnexal mass. The American College of Radiology recommendations are stratified based on menopausal status, benign-appearing characteristics, and size of the mass<sup>28</sup> (Figure 1<sup>4</sup>).

Gynecologic oncologists are trained to appropriately stage and debulk ovarian cancers. Prompt referral to a gynecologic oncologist is recommended for postmenopausal women with an elevated CA 125 level, a pelvic mass, evidence of abdominal or distant metastases, or ascites; and for premenopausal women with highly elevated CA 125 levels, ascites, or evidence of abdominal or distant metastases.<sup>1</sup> Despite being ineffective and unvalidated as a screening tool, serial ultrasonography should

**Table 4. Risk of Malignancy Index Scoring System in the Evaluation of an Adnexal Mass**

**RMI\* = U × M × CA 125**

Ultrasound characteristics

- Bilateral lesions
- Evidence of metastases
- Evidence of solid areas
- Multilocular cyst
- Presence of ascites

If none of these characteristics are found, U = 0

If one, U = 1

If two or more, U = 3

Menopausal status

- If premenopausal, M = 1
- If postmenopausal, M = 3

Serum CA 125 level (U per mL [kU per L])

Variations on RMI†

- In RMI2, postmenopausal status = 4, and if two or more radiologic characteristics are present, U = 4
- In RMI3, postmenopausal status = 3, and if two or more radiologic characteristics are present, U = 3

CA 125 = cancer antigen 125; M = menopausal status; RMI = Risk of Malignancy Index; U = ultrasound-based morphology score.

\*—The most common threshold for probability of malignancy is greater than 200.

†—The sensitivity and specificity of RMI2 and RMI3 are comparable with the original index (79.2% and 91.7%, respectively). Clinician preference should guide selection of which version to use in practice.

Adapted with permission from Dodge JE, Covens AL, Lacchetti C, et al.; Gynecology Cancer Disease Site Group. Management of a suspicious adnexal mass: a clinical practice guideline. *Curr Oncol*. 2012;19(4):e257.

be used to monitor a suspected benign adnexal mass.<sup>1,26</sup> No consensus guidelines exist for how often and how long to monitor.<sup>2,23</sup> If an adnexal mass persists for longer than 12 weeks, referral to a gynecologist is indicated. Surgery is the ultimate diagnostic tool. Up to 10% of women will have surgery for an ovarian finding in their lifetime.<sup>26</sup>

**Data Sources:** An online search of PubMed was conducted for meta-analyses, randomized controlled trials, clinical trials, and reviews using these key words: adnexal mass, adnexal masses, ovarian cancer, ovarian cancer and ultrasound, and CA 125. The U.S. Preventive Services Task Force, American College of Radiology Appropriateness Criteria, and the Cancer Care Ontario evidence-based management guideline were reviewed and pertinent articles retrieved. Essential Evidence Plus was also reviewed. The Cochrane database did not have a review pertinent to the focus of this paper. Search dates: October 2014 through January 2015.
