Screening for Impaired Visual Acuity in Older Adults: Recommendation Statement

As published by the U.S. Preventive Services Task Force.

This summary is one in a series excerpted from the Recommendation Statements released by the USPSTF. These statements address preventive health services for use in primary care clinical settings, including screening tests, counseling, and preventive medications.

The complete version of this statement, including supporting scientific evidence, evidence tables, grading system, members of the USPSTF at the time this recommendation was finalized, and references, is available on the USPSTF website at http://www.uspreventiveservicestaskforce.org/.

This series is coordinated by Sumi Sexton, MD, Associate Deputy Editor.

Summary of Recommendation and Evidence
The USPSTF concludes that the current evidence is insufficient to assess the balance of benefits and harms of screening for impaired visual acuity in older adults (Table 1). See the Clinical Considerations for suggestions for practice regarding the I statement.

Rationale

IMPORTANCE
Impairment of visual acuity is a serious public health problem in older adults. In 2011, about 12% of U.S. adults aged 65 to 74 years and 15% of those 75 years or older reported having problems seeing, even with glasses or contact lenses.

DETECTION
The USPSTF found convincing evidence that screening with a visual acuity test can identify persons with a refractive error. The USPSTF found convincing evidence that screening questions are not as accurate as visual acuity testing for assessing visual acuity. The USPSTF found adequate evidence that visual acuity testing alone does not accurately identify early age-related macular degeneration (AMD) or cataracts.

BENEFITS OF DETECTION AND EARLY TREATMENT
The USPSTF found inadequate overall evidence on the benefits of screening, early detection, and treatment to provide a coherent assessment of the overall benefits. Several studies evaluated the direct benefit of screening and reported no reductions in vision disorders or vision–related function in screened populations; however, these studies had limitations, including differing control interventions, high loss to follow-up, and low uptake of treatment. The USPSTF found adequate evidence that early treatment of refractive error, cataracts, and AMD improves or prevents loss of visual acuity.

HARMs OF DETECTION AND EARLY TREATMENT
The USPSTF found inadequate evidence on the harms of screening. The USPSTF found adequate evidence that early treatment of refractive error, cataracts, and AMD may lead to harms that are small to none.

USPSTF ASSESSMENT
The USPSTF concludes that the evidence is insufficient to assess the balance of benefits and harms of screening for impaired visual acuity in older adults. The evidence is lacking to provide a coherent assessment, and the balance of benefits and harms cannot be determined.

Clinical Considerations

PATIENT POPULATION UNDER CONSIDERATION
This recommendation applies to asymptomatic adults 65 years or older who do not present to their primary care clinician with vision problems.

SUGGESTIONS FOR PRACTICE REGARDING THE I STATEMENT

Potential Preventable Burden. In 2011, about 12% of U.S. adults aged 65 to 74 years and 15% of those 75 years or older reported having problems seeing, even with glasses or contact lenses.1 The prevalence of AMD is 6.5% in adults older than 40 years and increases with age (2.8% in those aged 40 to 59 years and 13.4% in those aged ≥ 60 years).2 About half of all cases of bilateral low vision (i.e., best-corrected visual acuity of < 20/40) in adults 40 years and older are caused by...
cataracts. The prevalence of cataracts increases sharply with age; an estimated 50% of U.S. adults 80 years or older have cataracts. The prevalence of hyperopia requiring a correction of +3.0 diopters or more ranges from about 5.9% in U.S. adults aged 50 to 54 years, to 15.2% in adults aged 65 to 69 years, to 20.4% in adults 80 years or older.

Older age is an important risk factor for most types of visual impairment. Additional risk factors for cataracts are smoking, alcohol use, ultraviolet light exposure, diabetes, corticosteroid use, and black race. Risk factors for AMD include smoking, family history, and white race.

**Screening tests**

A visual acuity test (such as the Snellen eye chart) is the usual method for screening for visual acuity impairment in the primary care setting. Screening questions are not as accurate as visual acuity testing. Evidence on other tests is lacking.

**Treatment and interventions**

Treatments include corrective lenses for refractive error; surgical removal of cataracts; laser photocoagulation, verteporfin, and intravitreal injections of vascular endothelial growth factor inhibitors for exudative (or wet) AMD; and antioxidant vitamins and minerals for dry AMD.

The USPSTF concludes that there is insufficient evidence to assess the balance of benefits and harms of screening for impaired visual acuity in older adults.

The USPSTF has made recommendations on screening for glaucoma and interventions to prevent falls in community-dwelling older adults. These recommendations are available on the USPSTF website (http://www.uspreventiveservicestaskforce.org).

**NOTE:** For a summary of the evidence systematically reviewed in making this recommendation, the full recommendation statement, and supporting documents, go to http://www.uspreventiveservicestaskforce.org.

AMD = age-related macular degeneration; USPSTF = U.S. Preventive Services Task Force.

**Screening Tests**

A visual acuity test (e.g., the Snellen eye chart) is the usual method for screening for visual acuity impairment in the primary care setting. Screening questions are not as accurate as visual acuity testing for identifying visual acuity impairment. Evidence on the use of other tests for vision screening in primary care, such as the pinhole test (a test for refractive error), the Amsler grid (a test of central vision to detect AMD), genetic testing, or funduscopy (visual inspection of the interior of the eye), is lacking.
TREATMENT
Several types of treatment are effective for improving visual acuity. Corrective lenses improve visual acuity in patients with a refractive error. Treatment of cataracts through surgical removal of the cataract is effective for improving visual acuity. Treatment of exudative (or wet) AMD includes laser photocoagulation, verteporfin, and intravitreal injections of VEGF inhibitors. Antioxidant vitamins and minerals are an effective treatment for dry AMD.

OTHER APPROACHES TO PREVENTION
This recommendation statement does not include screening for glaucoma. The USPSTF’s recommendations on screening for glaucoma and falls prevention are available on its website (http://www.uspreventiveservicestaskforce.org).

This recommendation statement was first published in JAMA. 2016;315(9):908-914.

The USPSTF recommendations are independent of the U.S. government. They do not represent the views of the Agency for Healthcare Research and Quality, the U.S. Department of Health and Human Services, or the U.S. Public Health Service.
