Exercise Prescriptions in Older Adults
PEARL GUOZHU LEE, MD, MS; ELIZABETH A. JACKSON, MD, MPH; and CAROLINE R. RICHARDSON, MD
University of Michigan School of Medicine, Ann Arbor, Michigan

Regular physical activity and exercise are important for healthy aging and are beneficial for chronic disease management. Exercise prescriptions for older adults should account for the individual’s health status and functional capacity. Any amount of exercise is better than being sedentary, even if health status prevents a person from achieving recommended goals. For most health outcomes, more benefits occur with physical activity performed at higher intensity, greater frequency, or longer duration. Guidelines recommend at least 150 minutes of moderate-intensity aerobic activity or 75 minutes of vigorous-intensity aerobic activity and at least two days of muscle-strengthening activities per week. Key components of the prescription include setting achievable activity goals, identifying barriers and providing potential solutions, and providing specific recommendations on the type, frequency, and intensity of activities. Older adults will derive distinct benefits from aerobic exercise, strength or resistance training, flexibility or stretching exercises, and balance training. Many community resources are available to help older adults begin a more active lifestyle. (Am Fam Physician. 2017;95(7):425-432. Copyright © 2017 American Academy of Family Physicians.)

The benefits of regular physical activity and exercise on general health and overall quality of life in older adults are well established,1 and these benefits are particularly salient among patients with chronic medical conditions such as osteoarthritis or cardiovascular disease (CVD).2 However, in 2013, more than 33% of adults 65 years or older reported no leisure-time physical activities.1 Only 16% of older adults met national guideline recommendations for physical activity, which are at least 150 minutes of moderate-intensity aerobic activity or 75 minutes of vigorous-intensity aerobic activity and two or more days of muscle-strengthening activities per week.1 Barriers to exercise include a lack of knowledge, lack of motivation, and poor health.2

Many primary care physicians agree that counseling to promote physical activity and a healthy diet is important to their patients.3 The U.S. Preventive Services Task Force recommends that primary care physicians provide behavioral counseling to promote a healthful diet and physical activity for CVD prevention in adults with CVD risk factors.4 This article reviews the recent evidence supporting physical activity among older adults, and aims to help physicians effectively counsel older patients to increase physical activity.

Important Considerations in Older Adults
Older adults are heterogeneous with respect to their health status and physical function.5 Normal aging is associated with reduced functional capacity and strength, and degenerative musculoskeletal conditions. Older adults at any submaximal exercise load tend to exert at a higher percentage of their maximal capacity and effort than younger persons.6 Additionally, older adults are more likely than younger adults to engage in physical activities at lower intensities.7 Although many older adults are functionally independent and able to participate in most exercise programs, others may have multiple chronic diseases and geriatric conditions, such as cognitive impairment and recurrent falls, limiting their ability to participate in certain types of exercise.5

Exercise in Older Adults

Sedentary behavior vs. physical activity

Sedentary time increases with older age, and excessive time spent in sedentary behavior, such as sitting, is associated with deleterious health outcomes including abnormal glucose metabolism and increased mortality. Reducing sedentary time, independent of physical activity, has known cardiovascular, metabolic, and functional benefits in older adults. One study found that among men 71 years or older whose physical activity exceeded current guidelines, more time spent in sedentary behavior was associated with greater mortality risk. Any amount of exercise is better than being sedentary, even if the individual’s health status prevents the achievement of recommended goals.

Key Components of an Exercise Prescription

For most health outcomes, benefits increase as the amount of physical activity increases through higher intensity, greater frequency, or longer duration. A verbal or written recommendation for physical activity should include a specific activity (modality), its frequency and intensity, and short- and long-term goals to help maintain motivation.

Common terms in an exercise prescription and examples of different types of physical activities are described in Table 1. Recommendations by the American College of Sports Medicine (ACSM) and U.S. Department of Health and Human Services (HHS) are listed in Table 2.

Physical activity prescriptions can first target increasing activity time, reducing sedentary time, or both, and then later increasing the intensity of the activity. In the beginning, the intensity and duration of physical activity should be low for older adults who are deconditioned or have physical function limitations, and then increased slowly as tolerated. For frail individuals, muscle strengthening activities and balance training may need to precede aerobic training activities.

Goal Setting

The initial adoption of physical activity is best predicted by readiness to change. Before writing an exercise prescription, physicians should educate the patient about the benefits of physical activity and motivate him or her with relevant personal goals, such as improving physical function or fitness, weight management, improving chronic disease management, and preventing falls. Once the patient is ready to start a physical activity program, the physician should help the patient set achievable goals (e.g., aim to increase brisk walking by 50 minutes a week rather than running three miles a day).
Physicians should instruct the patient to begin with activities that he or she can actually perform. The content and goals of the prescription need to be tailored individually to accommodate health status and functional capacity. The activities may be unstructured, such as activities of daily living (e.g., climbing stairs, walking to do an errand), or exercise programs, which are planned, structured, and repetitive movements to improve or maintain physical fitness (e.g., aerobics class, weight-lifting program). The four main categories of physical activities are aerobic/endurance, resistance/strength, balance, and flexibility exercises (Table 1).

Older adults who are not familiar with exercise training may benefit from working with an experienced fitness trainer. A trainer who has experience working with older adults and is certified by an accredited organization such as the ACSM can educate patients on the benefits of exercise, as well as the optimal frequency, intensity, and

Table 1. Common Terms in an Exercise Prescription and Examples of Physical Activities

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exercise</td>
<td>Planned, structured, and repetitive movement to improve or maintain one or more components of physical fitness</td>
</tr>
<tr>
<td>Intensity</td>
<td>Absolute intensity is the amount of energy used by the body per minute of activity, objectively measured as a metabolic equivalent, or MET; 1 MET = the amount of energy used in a resting state, like sitting or sleeping Relative intensity is the level of effort required to do an activity, as rated by the individual doing the activity; on a 10-point scale, sitting = 0 and working as hard as possible = 10</td>
</tr>
<tr>
<td>Light intensity (e.g., casual walking, light housework, stretching)</td>
<td>&lt; 3 METs</td>
</tr>
<tr>
<td>Moderate intensity (e.g., brisk walking, water aerobics, ballroom dancing, gardening)</td>
<td>3 to 5.9 METs, or the individual will breathe harder with a faster heart beat; the individual should be able to talk but not sing; on a 10-point scale, a moderate-intensity activity would be rated as 5 to 6</td>
</tr>
<tr>
<td>Vigorous intensity (e.g., jogging or running, aerobic dancing, heavy gardening)</td>
<td>≥ 6 METs, or the individual will not be able to say more than a few words without pausing for a breath</td>
</tr>
<tr>
<td>Physical activity</td>
<td>Body movement that is produced by the contraction of skeletal muscles and that increases energy expenditure</td>
</tr>
<tr>
<td>Aerobic/endurance exercise</td>
<td>Exercise in which the body’s large muscles move in a rhythmic manner for sustained periods</td>
</tr>
<tr>
<td>Balance training (e.g., backward, sideways, heel, or toe walking; tai chi)</td>
<td>A combination of activities designed to increase the individual’s lower body strength and reduce the likelihood of falling</td>
</tr>
<tr>
<td>Flexibility exercise (e.g., stretching hamstring, calves, or triceps)</td>
<td>Activities designed to preserve or extend range of motion around a joint</td>
</tr>
<tr>
<td>Resistance/strength exercise</td>
<td>Exercise that causes muscles to work or hold against an applied force or weight</td>
</tr>
<tr>
<td>(e.g., exercises using resistance bands, weight machines, handheld weights; digging, lifting, and carrying as part of gardening; carrying groceries)</td>
<td></td>
</tr>
<tr>
<td>Physical function</td>
<td>The capacity to carry out the physical activities of daily living; physical function reflects motor function and control, physical fitness, and habitual physical activity</td>
</tr>
<tr>
<td>Sedentary behavior</td>
<td>Activity that involves little or no movement or activities that are considered posture (e.g., sitting), having an energy expenditure of ≤ 1.5 METs</td>
</tr>

duration of each type of exercise. A trainer can also help decrease the fear of injury from exercise. For patients with physical function limitations, such as gait impairment, physical therapy may help to restore physical function to prepare for exercise. Table 3 demonstrates the key components of the exercise prescription.

AEROBIC AND RESISTANCE EXERCISE

Aerobic exercises have numerous cardiovascular and musculoskeletal benefits for older adults, and resistance exercise training is the only therapy known to consistently improve muscle mass, strength, power, and quality, as well as overall physical function in older adults. Aging is associated with a decline in muscle strength and muscle power, which is a combination of force and speed. These changes can be described by muscle quality, measured as the force produced per unit of active muscle mass, which estimates the contribution from muscle mass, neuromuscular function, and mechanical, contractile, and architectural properties of muscle. The ACSM recommends that older adults perform the following each week: a minimum of 150 minutes of moderate-intensity aerobic activity or 75 minutes of vigorous-intensity aerobic activity, and two or more nonconsecutive days of moderate-intensity strengthening activities, with eight to 10 exercises involving the major muscle groups and eight to 12 repetitions of each exercise. This recommendation is consistent with the 2008 HHS Physical Activity Guidelines for Americans.

FLEXIBILITY OR STRETCHING EXERCISES

Older adults with reduced joint flexibility may have difficulty performing daily activities such as dressing and reaching objects on a shelf. Flexibility or stretching exercises improve joint range of motion after three to four weeks of regular stretching at two to three times per week, but even greater gains are achieved with daily flexibility exercises. Flexibility exercise is most effective when performed after light-to-moderate aerobic or resistance exercise. Patients with recent joint injuries or surgery should consult with their physicians before performing flexibility exercises to avoid worsening injuries or impairing the healing of surgical wounds.

BALANCE AND PROPRIOCEPTIVE TRAINING

Balance and proprioceptive training should be a regular part of exercise for all older adults to prevent falls, especially in individuals at higher fall risk. Balance training involves practicing to control movements of the body’s position while standing, but with reducing base of support (e.g., standing on one foot). Balance training should be

---

Table 2. Recommendations for Physical Activity in Older Adults

| Avoid inactivity. Some physical activity is better than none. The intensity and duration of physical activity should be low at the outset for older adults who are highly deconditioned, functionally limited, or have chronic conditions that affect their ability to perform physical tasks. The progression of activities should be individualized and tailored to the individual’s tolerance and preferences. Muscle strengthening activities and balance training may need to precede aerobic training activities among very frail individuals. Older adults should exceed the recommended minimum amounts of physical activity if they desire to improve their fitness. Minimum weekly activity to achieve important health benefits:  
Two hours and 30 minutes (150 minutes) of moderate-intensity aerobic activity (e.g., brisk walking), plus muscle-strengthening activities for at least two days or 
One hour and 15 minutes (75 minutes) of vigorous-intensity aerobic activity (e.g., jogging, running), plus muscle-strengthening activities for at least two days or 
A combination of moderate- and vigorous-intensity aerobic activities equivalent to the recommendations above, plus muscle-strengthening activities for at least two days. |

15

Flexibility exercises (static movements) should be performed at least two days per week at moderate intensity, preferably after aerobic or resistance exercises. Older adults at risk of falling should do balance training for three or more days per week.

---

NOTE: The American College of Sports Medicine guidelines were developed by an expert panel after evaluating the strength of available scientific evidence based on the rating system from the National Heart, Lung, and Blood Institute (A through D).

*—Moderate-intensity activity requires a medium level of effort. On a scale of 0 to 10, where sitting is 0 and the greatest effort possible is 10, moderate-intensity activity is a 5 or 6 and produces noticeable increases in respiratory and heart rates.

†—Vigorous-intensity activity is a 7 or 8 on a scale of 0 to 10 and produces large increases in respiratory and heart rates.

Information from references 13 and 16.
practiced at least two hours per week, should be ongoing for lasting fall prevention effect, and may be group based or home based. To minimize the risk of falling during exercise, balance training should be closely supervised at first and begin with less challenging postures.

Monitoring Progress
After the patient begins a physical activity program, the physician should continue to monitor the progress periodically (e.g., at least once per year), provide encouragement, and help the patient overcome barriers such as lack of time or fatigue. Pedometer use has been shown to significantly increase physical activity if a step goal is set. The goal can be incremental increases of daily steps from baseline (e.g., by 10% every two weeks), or increases of daily walking time (e.g., by 10 minutes per day) until a step goal is reached.

Older Adults with Chronic Medical Conditions
Older adults with chronic medical conditions can benefit from participating in regular physical activities (Table 4). Despite the concern for the risk of exercise-related cardiovascular events, stress testing is unnecessary for older adults who plan to participate in low- or moderate-intensity physical activities. Stress testing is recommended before vigorous exercise training in persons with known CVD. Physical activity may be contraindicated or restricted in a few medical conditions (e.g., decompensated congestive heart failure, severe aortic stenosis).

OSTEOARTHRITIS
Land- and aquatic-based physical activities help patients with knee or hip osteoarthritis to reduce pain and increase mobility, muscle strength, joint flexibility, and aerobic endurance. The buoyancy of the water decreases joint loading, which can help decrease pain, and warm water may have a therapeutic effect. Once patients become more mobile, they can transition to land-based exercises. Land-based exercise improves pain and functional aerobic capacity more than aquatic activities.

DIABETES MELLITUS
Regular physical activity as part of a lifestyle intervention can help prevent diabetes mellitus; reduce physical functioning impairment among older patients with diabetes; improve glucose levels, lipid levels, and blood pressure control; and enhance weight loss. Physical activity programs that include aerobic and resistance training have demonstrated improvement in A1C levels more than aerobic or resistance training alone. The ACSM and the American Diabetes Association recommend that previously sedentary individuals with diabetes who want to undertake activity more intense than brisk walking and individuals who

<td>For 2 days per week (frequency), lift 5-lb dumbbells, front arm and side arm raises (activity, muscle groups) for 2 sets of 5 repetitions each day at home (setting).</td>
</tr>
</tbody>
</table>

**Weeks 3 and 4 (increase duration of aerobic activity and add more resistance training)**

| **Aerobic activities** | For 3 days per week (frequency), walk briskly (activity, intensity) for 30 minutes (duration) each day at the local park after dinner (setting). |
| **Flexibility training** | For 3 days per week (frequency), stretch calf and thigh muscles (activity, muscle groups) for 5 minutes each day at home (setting) after walking (aerobic activity). |
| **Resistance training** | For 2 days per week (frequency), lift 5-lb dumbbells, front arm and side arm raises, and perform wall push-ups (activity, muscle groups) for 2 sets of 10 repetitions each day at home (setting). |

**NOTE:** Sample exercise prescription for an older adult with diabetes mellitus treated with glipizide (Glucotrol) who currently performs less than 150 minutes of moderate-intensity physical activity per week. Frequency, activity, muscle group, and setting should be tailored to the individual patient.

*—Caution to the patient: Keep some food readily available in case your blood sugar gets low. Try to exercise within two hours of eating a meal. Take breaks during activities if necessary.
Table 4. Physical Activity Recommendations for Patients with Specific Medical Conditions

<table>
<thead>
<tr>
<th>Medical Condition</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arthritis/musculoskeletal pain(^{21,27})</td>
<td>Evidence supports land- or aquatic-based physical activity(^{28,29}) &lt;br&gt;Aerobic training three to five times per week and resistance training two to three times per week &lt;br&gt;Aerobic exercises (e.g., walking or cycling), lower extremity strengthening exercises, tai chi, and aquatic exercises (e.g., aerobics, strength training performed in a therapeutic/heated indoor pool) can all alleviate pain and improve function in patients with osteoarthritis(^{27})</td>
</tr>
<tr>
<td>Cardiovascular disease (includes peripheral vascular occlusive disease)</td>
<td>For peripheral vascular occlusive disease, patients may need to exercise to the limits of pain tolerance each session to extend time to claudication &lt;br&gt;Stress testing is recommended before vigorous exercise training in persons with known cardiovascular disease(^{16})</td>
</tr>
<tr>
<td>Diabetes mellitus(^{10})</td>
<td>Aerobic training at least three days per week with no more than two consecutive days between bouts of activity (i.e., 150 minutes per week of moderate to vigorous activities) &lt;br&gt;Resistance training at moderate to vigorous intensity at least twice per week on nonconsecutive days(^{10}) &lt;br&gt;If the individual is using insulin or insulin secretagogues, decrease the medication doses before, during, and after exercise, and/or ingest carbohydrates if preexercise blood glucose levels are less than 100 mg per dL (5.6 mmol per L)</td>
</tr>
<tr>
<td>Falls</td>
<td>For patients at risk of falls, balance exercises are recommended for fall prevention(^{16}) &lt;br&gt;Additional effective fall prevention programs are multifaceted interventions that include gait training and strength training, tai chi, Otago Exercise Program, and Stepping On(^{31})</td>
</tr>
<tr>
<td>Obesity</td>
<td>Aerobic exercises contribute to energy expenditure to induce caloric deficit &lt;br&gt;Resistance exercises are recommended during weight-loss period to help maintain lean muscle and bone mineral density(^{32})</td>
</tr>
<tr>
<td>Osteoporosis(^{33,34})</td>
<td>Most evidence supports resistance exercises; some evidence supports high-intensity and high-impact aerobic exercises &lt;br&gt;Add balance training to prevent falls</td>
</tr>
<tr>
<td>Pulmonary disease(^{35})</td>
<td>Exercise training is a part of the pulmonary rehabilitation program (usually six to 12 weeks) for patients with chronic obstructive pulmonary disease &lt;br&gt;Exercise sessions should be timed to coincide with bronchodilator medication peak; use oxygen during exercise as needed</td>
</tr>
</tbody>
</table>

**NOTE:** A combination of aerobic and resistance training at moderate intensity is usually recommended for optimal health benefits. <br>Information from references 16, 21, and 27 through 35.
