FPIN’s Help Desk Answers

Predictors of Acute Myocardial Infarction

JARED WEST, DO, and SARAH DALY, DO, FAAFP, Utah Valley Family Medicine Residency, Provo, Utah

Clinical Question
What elements of a patient’s chest pain history are the best predictors for ruling in/out acute myocardial infarction (MI)?

Evidence-Based Answer
The most useful element for ruling in acute MI is chest pain with radiation to both arms, followed by radiation to the right arm. The most useful elements for ruling out acute MI are pleuritic chest pain, sharp pain, and pain reproduced by palpation. (Strength of Recommendation = A, based on two systematic reviews and one cohort study.)

Evidence Summary
A systematic review of 64 published studies and one unpublished study (N not reported) reviewed bedside diagnosis of MI in adults presenting to the emergency department with chest pain unrelated to trauma and unexplained by radiography.1 The diagnosis of acute MI was determined by elevated cardiac enzymes, ECG changes, and one unpublished study (N not reported), sharp or stabbing pain (LR+ = 0.2; 95% CI, 0.2 to 0.3), pain reproduced by palpation (LR+ = 0.2 to 0.4; CI not reported), sharp or stabbing pain (LR+ = 0.3; 95% CI, 0.2 to 0.5), and positional pain (LR+ = 0.3; 95% CI, 0.2 to 0.4).

A prospective observational cohort study (N = 893) examined clinical features of acute MI in patients presenting to the large urban emergency department of a teaching hospital.3 The characteristic that most reliably predicted acute MI was pain radiation to both arms or shoulders (sensitivity = 38.2%; specificity = 90.6%; LR+ = 4.1; 95% CI, 2.5 to 6.5). The factor associated with a decreased likelihood was a tender chest wall (sensitivity = 92%; specificity = 28%; LR+ = 0.3; 95% CI, 0.1 to 1.1).
