Interventions to Prevent Perinatal Depression: Recommendation Statement

Summary of Recommendation and Evidence
The USPSTF recommends that clinicians provide or refer pregnant and postpartum persons who are at increased risk of perinatal depression to counseling interventions (Table 1). B recommendation.

See the Clinical Considerations section for information on risk assessment.

Rationale

IMPORTANCE
Perinatal depression, which is the occurrence of a depressive disorder during pregnancy or following childbirth, affects as many as 1 in 7 women and is one of the most common complications of pregnancy and the postpartum period.\(^1\) It is well established that perinatal depression can result in negative short- and long-term effects on both the woman and child.\(^2\)

BENEFITS OF COUNSELING INTERVENTIONS
The USPSTF found convincing evidence that counseling interventions, such as cognitive behavior therapy and interpersonal therapy, are effective in preventing perinatal depression in those at increased risk.

HARMS OF COUNSELING INTERVENTIONS
The USPSTF found adequate evidence to bound the potential harms of counseling interventions as no greater than small, based on the nature of the interventions and the low likelihood of serious harms.

USPSTF ASSESSMENT
The USPSTF concludes with moderate certainty that counseling interventions to prevent perinatal depression have a moderate net benefit for persons at increased risk.

Clinical Considerations

PATIENT POPULATION UNDER CONSIDERATION
This recommendation applies to pregnant persons and persons who are less than 1 year postpartum who do not have a current diagnosis of depression but are at increased risk of developing depression.

ASSESSMENT OF RISK
Clinical risk factors that may be associated with the development of perinatal depression include a personal or family history of depression, history of physical or sexual abuse, having an unplanned or unwanted pregnancy, current stressful life events, pregestational or gestational diabetes, and complications during pregnancy (e.g., preterm delivery, pregnancy loss). In addition, social factors such as low socioeconomic status, lack of social or financial support, and adolescent parenthood have also been shown to increase the risk of developing perinatal depression. However, there is no accurate screening tool for identifying women at risk of perinatal depression and who might benefit from preventive interventions.

A pragmatic approach, based on the populations included in the systematic evidence review, would be to provide counseling interventions to women with 1 or more of the following: a history of depression, current depressive symptoms (that do not reach a diagnostic threshold), certain socioeconomic risk factors such as low income or adolescent or single parenthood, recent intimate partner violence, or mental health–related factors such as elevated anxiety symptoms or a history of significant negative life events.

COUNSELING INTERVENTIONS
Studies on counseling interventions to prevent perinatal depression mainly included cognitive behavior therapy and interpersonal therapy.

Cognitive behavior therapy focuses on the concept that positive changes in mood and behavior can be achieved by

As published by the USPSTF.

This summary is one in a series excerpted from the Recommendation Statements released by the USPSTF. These statements address preventive health services for use in primary care clinical settings, including screening tests, counseling, and preventive medications.

The complete version of this statement, including supporting scientific evidence, evidence tables, grading system, members of the USPSTF at the time this recommendation was finalized, and references, is available on the USPSTF website at https://www.uspreventiveservicestaskforce.org/.

This series is coordinated by Kenny Lin, MD, MPH, Deputy Editor.

A collection of USPSTF recommendation statements published in AFP is available at https://www.aafp.org/afp/uspstf.
There is no accurate screening tool for identifying who is at risk of perinatal depression and who might benefit from preventive interventions. A pragmatic approach, based on the populations included in the systematic evidence review, would be to provide counseling interventions to women with 1 or more of the following risk factors: a history of depression, current depressive symptoms (that do not reach a diagnostic threshold), certain socioeconomic risk factors such as low income or adolescent or single parenthood, recent intimate partner violence, or mental health–related factors such as elevated anxiety symptoms or a history of significant negative life events.

Studies on counseling interventions to prevent perinatal depression mainly included cognitive behavior therapy and interpersonal therapy. The USPSTF found limited or mixed evidence that other studied interventions such as physical activity, education, pharmacotherapy, dietary supplements, and health system interventions were effective in preventing perinatal depression.

The USPSTF recommends screening for depression in adults, including pregnant and postpartum women. The USPSTF also recommends screening for depression in adolescents aged 12 to 18 years and found insufficient evidence to recommend for or against screening in children 11 years or younger.

There are no data on the ideal timing for offering or referral to counseling interventions; however, most were initiated during the second trimester of pregnancy. Ongoing assessment of risks that develop in pregnancy and the immediate postpartum period would be reasonable, and referral could occur at any time.

Counseling sessions reviewed for this recommendation ranged from 4 to 20 meetings (median: 8 meetings) lasting for 4 to 70 weeks. The format of counseling comprised mainly group and individual sessions, with the majority involving in-person visits. Intervention staff included psychologists, midwives, nurses, and other mental health professionals.

One example of a cognitive behavioral approach was the Mothers and Babies program. It involved 6 to 12 weekly 1- to 2-hour group sessions during pregnancy and 2 to 5 postpartum booster sessions. The program included modules on the cognitive behavior theory of mood and health; physiological effects of stress; behavior theory of mood and health; importance of pleasant and rewarding activities; how to reduce cognitive distortions and automatic thoughts; and the importance of social networks, positive mother–child attachment, and parenting strategies to promote child development and secure attachment in infants.

The Reach Out, Stand Strong, Essentials for New Mothers program is an example of an interpersonal therapy approach reviewed by the USPSTF. It involved 4 or 5 prenatal group sessions lasting 60 to 90 minutes and 1 individual 50-minute postpartum session. Course content included psychoeducation on the baby blues and postpartum depression, stress management, development of a social support system, identification of role transitions, discussion of types of

| Risk assessment | There is no accurate screening tool for identifying who is at risk of perinatal depression and who might benefit from preventive interventions. | Other relevant USPSTF recommendations | The USPSTF recommends screening for depression in adults, including pregnant and postpartum women. The USPSTF also recommends screening for depression in adolescents aged 12 to 18 years and found insufficient evidence to recommend for or against screening in children 11 years or younger. |
of interpersonal conflicts common around childbirth and techniques for resolving them, and role-playing exercises with feedback from other group members.

**ADDITIONAL APPROACHES TO PREVENTION OF DEPRESSION**

The Substance Abuse and Mental Health Services Administration–Health Resources and Services Administration Center for Integrated Health Solutions promotes the development of, and provides resources for, integrating primary and behavioral health services. The Substance Abuse and Mental Health Services Administration provides resources for locating mental health services. The Mothers and Babies program, based on cognitive behavior therapy, also provides web-based resources for families and clinicians.

The USPSTF has a related recommendation on screening for depression in adults, including pregnant and postpartum women (B recommendation). The USPSTF also recommends screening for depression in adolescents aged 12 to 18 years (B recommendation) and found insufficient evidence to recommend for or against screening in children 11 years or younger (I statement).

The USPSTF recommendations are independent of the U.S. government. They do not represent the views of the Agency for Healthcare Research and Quality, the U.S. Department of Health and Human Services, or the U.S. Public Health Service.
