### Professional Practice Gap

- Physicians have knowledge gaps with regard to evaluating acute abdominal pain, to evaluate for signs associated with causes of abdominal pain.
- Physicians have knowledge gaps in the selection of appropriate diagnostic imaging for the evaluation of abdominal pain.
- Physicians have knowledge gaps in identifying red flag symptoms in patients with acute abdominal pain that indicate emergent or urgent conditions that require surgical consult.

### Learning Objective(s) that will close the gap and meet the need

1. Narrow the differential diagnosis of acute abdominal pain based on the location of the pain and the age and sex of the patient.
2. Identify red flag symptoms in patients with acute abdominal pain that indicate emergent or urgent conditions that require surgical consult.
3. Order appropriate diagnostic and imaging studies based on the location of the pain and the presentation of the patient.
4. Recognize etiology of some more relevant causes of abdominal pain: ectopic pregnancy, appendicitis, bowel obstruction, choledocholithiasis, pediatric abdominal emergencies.

### Outcome Being Measured

Learners will submit written commitment to change statements on the session evaluation, indicating how they plan to implement presented practice recommendations.

**Faculty Instructional Goals**

Faculty play a vital role in assisting the AAFP to achieve its mission by providing high-quality, innovative education for physicians, residents and medical students that will
encompass the art, science, evidence and socio-economics of family medicine and to support the pursuit of lifelong learning. By achieving the instructional goals provided, faculty will facilitate the application of new knowledge and skills gained by learners to practice, so that they may optimize care provided to their patients.

- Provide up to 3 evidence-based recommended practice changes that can be immediately implemented, at the conclusion of the session; including SORT taxonomy & reference citations
- Facilitate learner engagement during the session
- Address related practice barriers to foster optimal patient management
- Provide recommended journal resources and tools, during the session, from the American Family Physician (AFP), Family Practice Management (FPM), and Familydoctor.org patient resources; those listed in the References section below are a good place to start
  - Visit http://www.aafp.org/journals for additional resources
  - Visit http://familydoctor.org for patient education and resources
- Provide updates on new treatment therapies, changes to therapies, or warnings associated with existing therapies. Provide recommendations regarding new FDA approved medications; including safety, efficacy, tolerance, and cost considerations relative to currently available options. **Include relevant FDA REMS education for any applicable medications.**
- Provide recommendations for treating patients presenting with abdominal pain in the urgent care or emergency care setting judiciously with appropriate analgesics.
- Provide specific evidence-based examples illustrating the appropriate pain treatment of patients presenting with abdominal pain in the urgent care or emergency care setting
- Provide specific case-based examples illustrating the differential diagnosis of acute abdominal pain
- Provide evidence-based examples illustrating appropriate diagnostic and imaging studies for patients presenting with abdominal pain
- Provide case-based examples illustrating the identification of “red flag” symptoms in patients presenting with acute abdominal pain.
- Provide recommendations regarding guidelines for Medicare reimbursement.
- Provide recommendations to maximize office efficiency and guideline adherence to the diagnosis and management of
- Provide an overview of newly available treatments, including efficacy, safety, contraindications, and cost/benefit relative to existing treatments.

**Needs Assessment**

Although abdominal pain is common and often benign, acute and severe abdominal pain is almost always a symptom of intra-abdominal disease. Approximately 1.6% of office visits and 8% of emergency department visits are for abdominal pain. Ten percent of patients presenting to the emergency department for abdominal pain have a severe or life-threatening cause for their abdominal pain and may require surgery. Approximately one-fourth of patients presenting to the emergency department are older than 50 years of age, and tend to present later in the course of their illness and have more nonspecific symptoms.
Data from a recent American Academy of Family Physicians (AAFP) CME Needs Assessment survey indicate that family physicians have knowledge gaps related to evaluating and managing abdominal pain, including selecting and interpreting appropriate imaging modalities. More specifically, CME outcomes data from 2013-2016 AAFP FMX (formerly Assembly): Acute and Chronic Abdominal Pain sessions suggest that physicians have knowledge and practice gaps with regard to evaluation, especially the inclusion of testicular exams in males and pregnancy tests for females of childbearing age presenting with abdominal pain; the identification of red flags for comorbid conditions; selection of appropriate laboratory and/or imaging tests; performing appropriate physical examination techniques; and strategies to increase guideline adherence.

The diagnosis of abdominal pain, especially acute appendicitis, is challenging in children, especially in infants and toddlers. Additionally, studies suggest a disparity of outcomes exists in the acute ED setting among children presenting with abdominal pain based on race and SES, with differences in appendicitis with perforation, length of stay, and time until surgery. Missed or delayed diagnosis can result in perforation, which can cause longer hospital stays, bowel obstruction, and sepsis. Abdominal and pelvic CT can be used in children to confirm or rule out acute appendicitis. However, CT is expensive and exposes the patient to ionizing radiation. For these reasons, physicians should consider using ultrasonography as the initial imaging modality. Ultrasonography is fast, safe, well tolerated, and does not expose the patient to radiation. It can confirm the diagnosis of acute appendicitis in children, but it cannot definitively rule out the condition. If the diagnosis remains uncertain after ultrasonography, CT can be performed.

Physicians may improve their care of patients with acute abdominal pain by engaging in continuing medical education that provides practical integration of current evidence-based guidelines and recommendations into their standards of care, including, but not limited to the following:

- The Alvarado score, Pediatric Appendicitis Score, or Appendicitis Inflammatory Response score can be used with point-of-care or formal ultrasonography and laboratory testing to help diagnose acute appendicitis and reduce the use of computed tomography.
- When skilled sonographers are available, first-line imaging for patients with suspected acute appendicitis consists of point-of-care or formal ultrasonography, especially in children and pregnant women.
- Opioids, nonsteroidal anti-inflammatory drugs, or acetaminophen should be provided to patients with suspected acute appendicitis.
- Open and laparoscopic appendectomies are effective surgical techniques for the treatment of acute appendicitis.
- Intravenous antibiotics can be used as first-line therapy in children and adults with acute appendicitis.
- Ultrasonography is the initial imaging study of choice for evaluating patients with acute right upper quadrant pain.
- Computed tomography is the initial imaging study of choice for evaluating patients with acute right lower quadrant or left lower quadrant pain.
- Conventional radiography has limited diagnostic value in the assessment of patients with acute abdominal pain.
• Beta human chorionic gonadotropin testing should be considered before performing diagnostic imaging in all women of reproductive age presenting with acute abdominal pain.
• A normal white blood cell count does not rule out appendicitis.
• Simultaneous amylase and lipase measurements are recommended in patients with epigastric pain.
• Abdominal radiography is an effective initial examination in patients with suspected intestinal obstruction.
• Consider cholecystitis even if an older patient does not present with classic symptoms, because they often are absent in older persons.
• Consider small bowel obstruction in the older patient with a history of surgery who presents with diffuse, colicky pain, nausea, vomiting, altered bowel sounds, distention, dehydration, diffuse tenderness, and possibly an ill-defined mass.
• Consider abdominal aortic aneurysm in the older patient with back or abdominal pain, particularly if they are male or have a history of tobacco use.
• Consider acute mesenteric ischemia if a patient presents with severe, poorly localized pain out of proportion to physical findings.
• Urinalysis, complete blood count, pregnancy test, and erythrocyte sedimentation rate or C-reactive protein should be the initial laboratory tests in the evaluation of acute abdominal pain in children.
• Ultrasonography is the first imaging choice for acute abdominal pain in children with suspected appendicitis or intussusception. While unnecessary radiation should be avoided; CT may still be required in some children with abdominal pain.
• Opiates may be safely used in children with acute abdominal pain without delaying or affecting the accuracy of diagnosis.
• Functional abdominal pain is a clinical diagnosis and therefore does not require a diagnostic workup.
• Alarm symptoms and laboratory and diagnostic workup findings do not reliably distinguish organic from nonorganic disease in children with recurrent abdominal pain. However, organic disease is suggested by the presence of fever, vomiting, blood in the stool, more than three alarm symptoms, or history of urinary tract infections.
• For all types of recurrent abdominal pain in children, the primary goals of management are improving quality of life, reducing parent and child concern about the seriousness of the condition, and reducing disability associated with pain rather than complete resolution of pain.
• In children with functional abdominal pain, the use of probiotics, such as Lactobacillus, reduces the intensity and frequency of abdominal pain and is safe in children.
• Cognitive behavior therapy and hypnotherapy improve abdominal pain in children with functional abdominal pain disorders.

Best practices in emergency medicine: Recommendations from the Choosing Wisely Campaign:14
• Computed tomography is not necessary in the routine evaluation of abdominal pain.
  (American Academy of Pediatrics)
• Do not do computed tomography for the evaluation of suspected appendicitis in children until after ultrasonography has been considered as an option. (American College of Surgeons)

Physicians can improve patient satisfaction with the referral process by using readily available strategies and tools such as, improving internal office communication, engaging patients in scheduling, facilitating the appointment, tracking referral results, analyzing data for improvement opportunities, and gathering patient feedback.¹⁷,¹⁸

These recommendations are provided only as assistance for physicians making clinical decisions regarding the care of their patients. As such, they cannot substitute for the individual judgment brought to each clinical situation by the patient's family physician. As with all clinical reference resources, they reflect the best understanding of the science of medicine at the time of publication, but they should be used with the clear understanding that continued research may result in new knowledge and recommendations. These recommendations are only one element in the complex process of improving the health of America. To be effective, the recommendations must be implemented. As such, physicians require continuing medical education to assist them with making decisions about specific clinical considerations.
